Department of Quantitative & Computational Biology
University of Southern California*

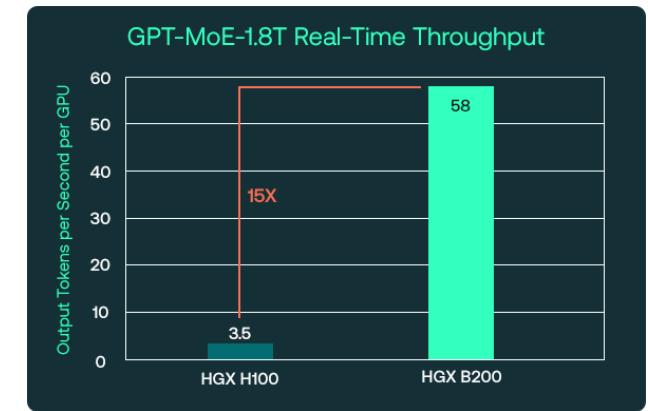

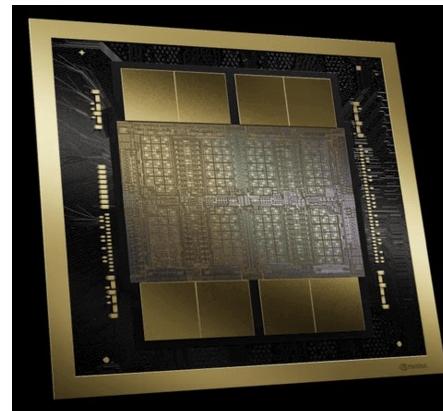

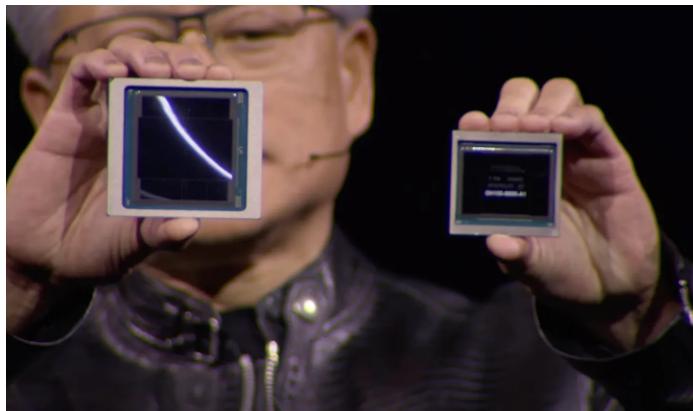

Email: anakano@usc.edu

Goal: Multithreading on graphics processing units (GPUs);
heterogenous device concept

Graphics Processing Unit (GPU)

- **GPU:** A specialized processor that offloads 3D graphics rendering from the central processing unit (CPU)
- **GPGPU:** General-purpose computing on GPU, by using a GPU to perform computation traditionally handled by the CPU; GPU is considered as a multithreaded, massively data parallel co-processor (accelerator)
- **NVIDIA Quadro, Tesla & newer GPUs are capable of general-purpose computing with the use of Compute Unified Device Architecture (CUDA)**

NVIDIA B200 (16,896 CUDA cores & 528 tensor cores)

CUDA

How to program GPGPU?

- **Compute Unified Device Architecture**
- **Integrated host (CPU) + device (GPU) application programming interface based on C language, developed at NVIDIA**
- **CUDA homepage**
http://www.nvidia.com/object/cuda_home.html
- **Widely used in the deep-learning community**
<https://www.deeplearningbook.org/contents/applications.html>

Using CUDA on Discovery

- Add the following commands in .bashrc in your home directory

```
module purge
module load usc
module load cuda
```

- Compilation

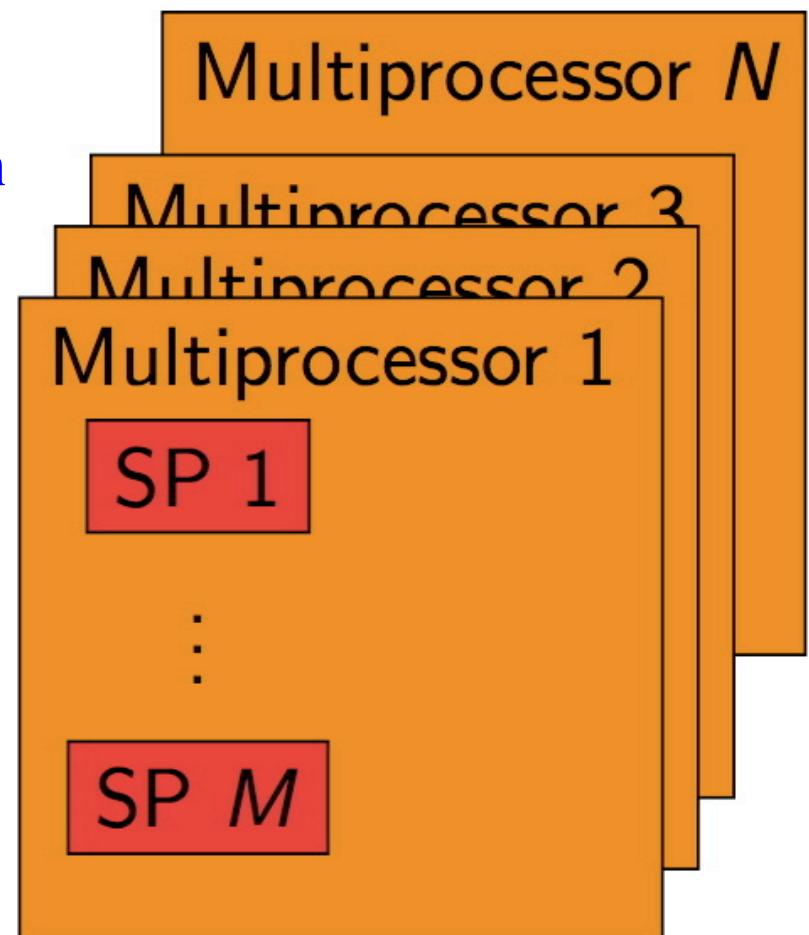

```
nvcc -o pi pi.cu
```

- Submit a Slurm script

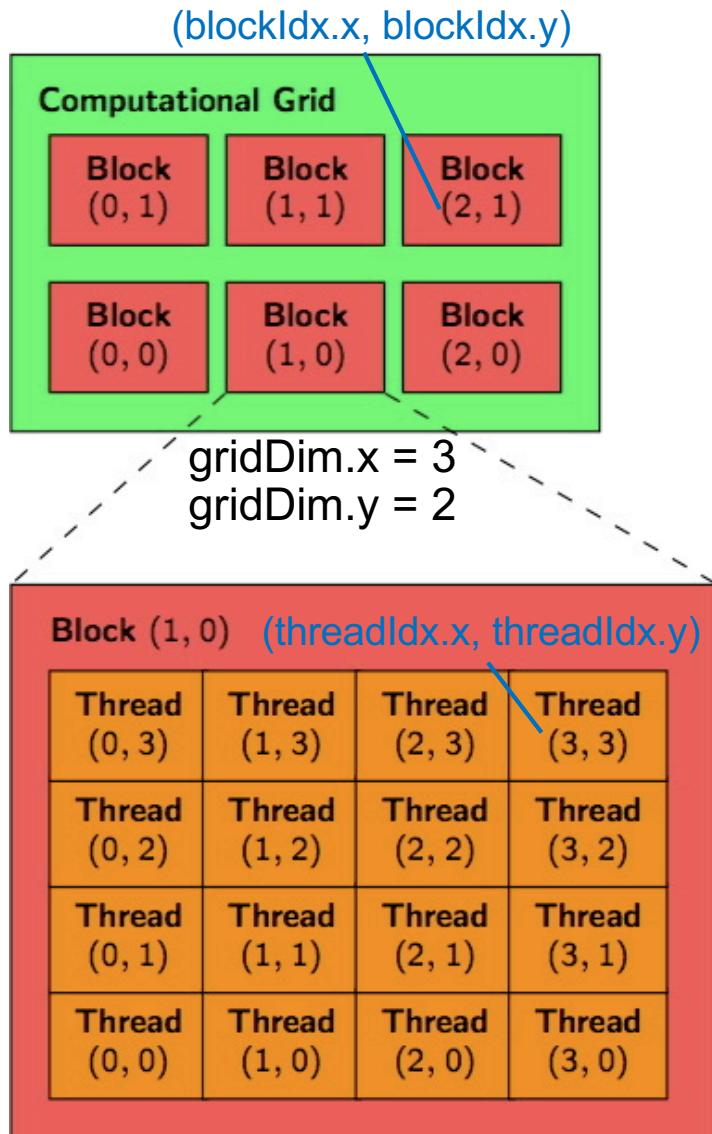

```
#!/bin/bash
#SBATCH --partition=gpu
#SBATCH --nodes=1
#SBATCH --ntasks-per-node=1
#SBATCH --cpus-per-task=1
#SBATCH --gpus-per-task=1
#SBATCH --time=00:00:59
#SBATCH --output=pi.out
#SBATCH -A anakano_429
./pi
```

Example of NVIDIA GPU at CARC

- Host (CPU)
 - > Dual octacore ($2 \times 8 = 16$) Intel Xeon
 - > Clock rate: 2.4 GHz
 - > Memory: 64 GB
- Device (GPU): Dual NVIDIA Tesla K20m
 - > Number of streaming multiprocessors (SMs) per GPU: 13
 - > Number of cores (or streaming processors, SPs) per SM: 192
 - > Total number of cores: $13 \times 192 = 2496$
 - > Clock rate: 706 MHz
 - > Global memory: 5 GB
 - > Shared memory per SM: 48 KB

Grid, Blocks & Threads

- Computational grid = a 1 or 2D grid of thread blocks (cf. SMs); each block = a 1, 2 or 3D array of ≤ 512 threads (cf. SPs); the application specifies the grid & block dimensions
 - **gridDim** provides dimension of grid;
1 or 2 element struct: “.x” & “.y”
 - **blockDim** provides dimension of block;
1, 2 or 3 element struct: “.x”, “.y” & “.z”
- All threads within a block execute the same kernel (SPMD) & cooperate via shared memory, atomic operations & barrier synchronization
- Each block has a unique block ID
 - **blockIdx** is 1 or 2 element struct
- Each thread has a unique ID within the block
 - **threadIdx** is a struct with up to 3 elements: “.x”, “.y” (in 2 or 3D) & “.z” (in 3D) for the innermost, intermediated & outermost index
- Each thread uses the block & thread IDs to decide what data to work on (i.e., SPMD)

cf. `vproc[3]`, `vthrd[3]`, `vid[3]`, `vtd[3]` in `hmd.c`

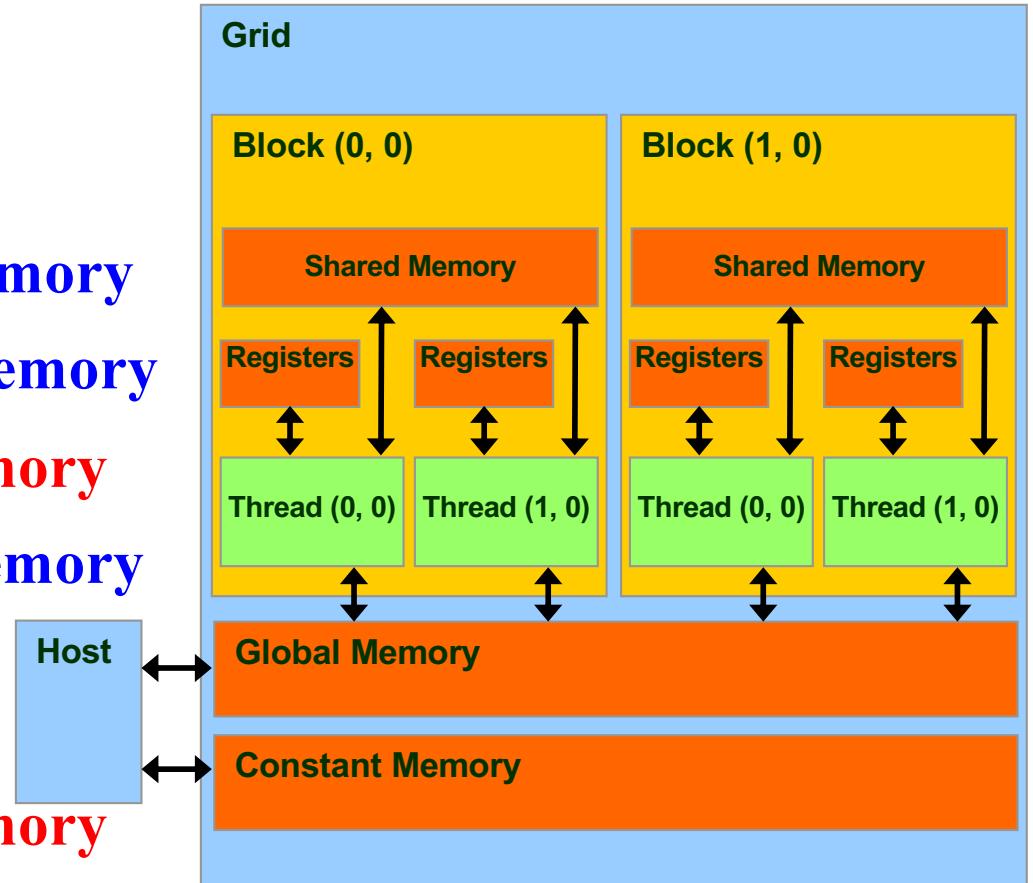

Hierarchical Device Memory

Each thread can:

- Read/write per-thread registers
- Read/write per-thread local memory
- Read/write per-block shared memory
- Read/write per-grid global memory
- Read only per-grid constant memory

Host code can:

- Read/write per-grid global memory
- Read/write per-grid constant memory

We will only use global device memory in assignment

Device Memory Allocation

cudaMalloc()

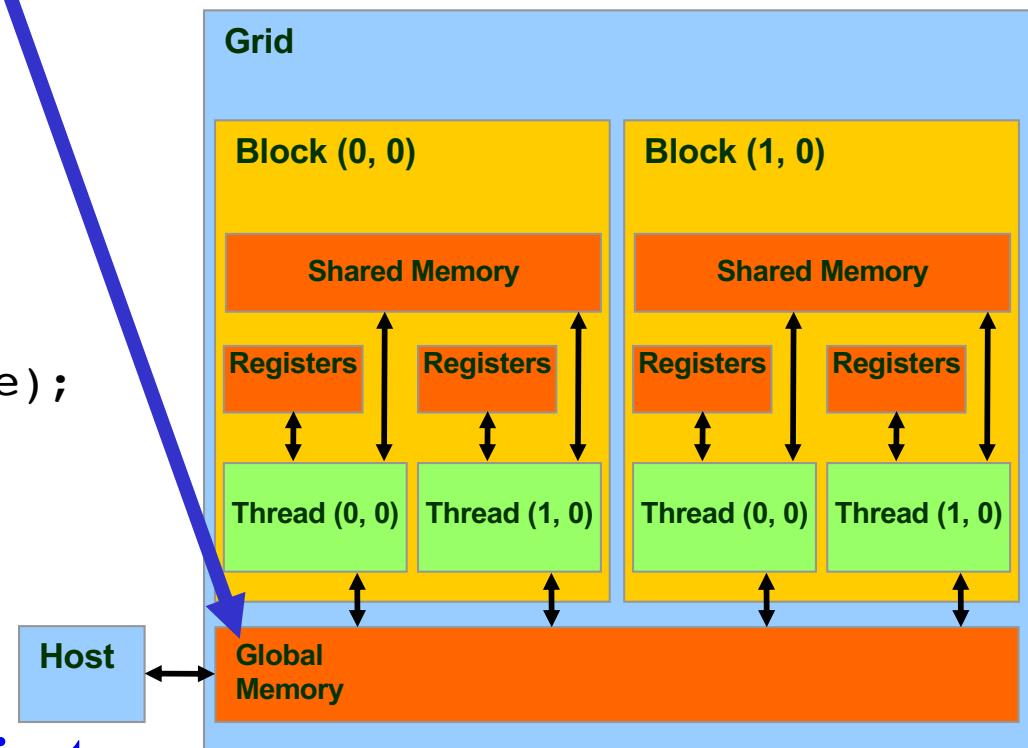

- Allocates object in the device global memory
- Requires two parameters:
 - Address of a pointer to the allocated object
 - Size of allocated object

```
cudaMalloc( (void **) &sumDev, size );
```

cudaFree()

- Frees object from device global memory
- Parameter: Pointer to freed object

```
cudaFree( sumDev );
```

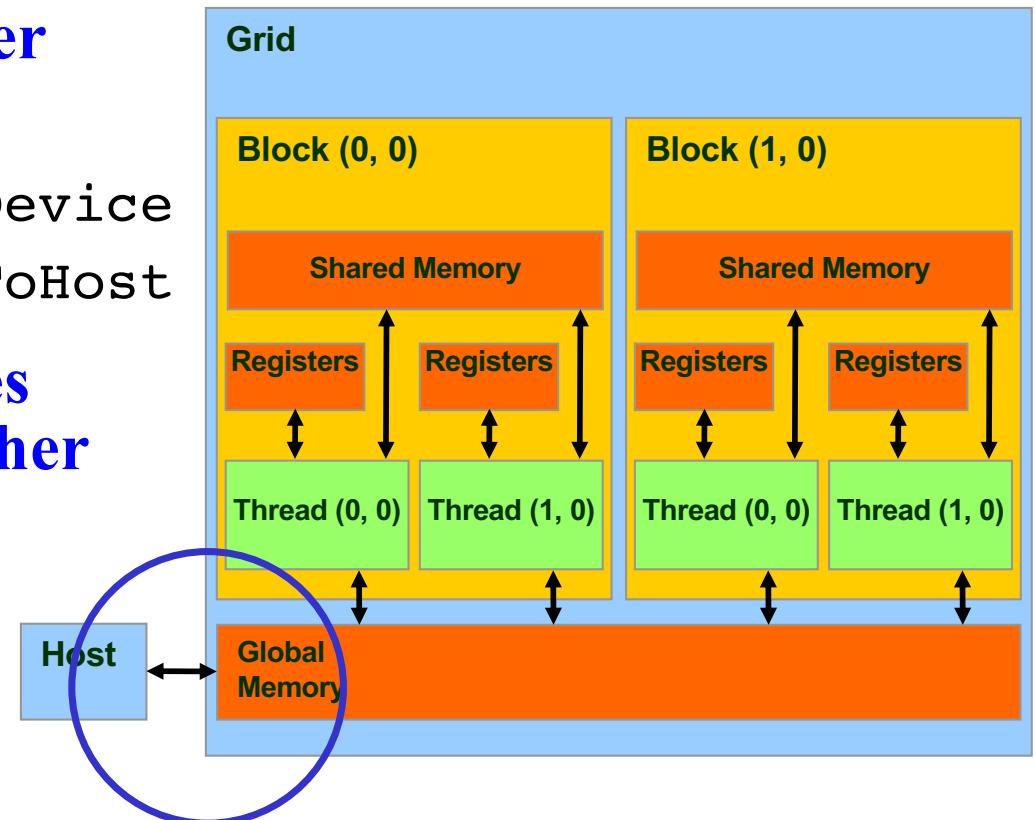

Host-Device Data Transfer

cudaMemcpy(dest, src, size, cmd)

- **Arguments**
 - dest = pointer to array to receive data
 - src = pointer to array to source data
 - size = # of bytes to transfer
 - cmd = transfer direction
 - > cudaMemcpyHostToDevice
 - > cudaMemcpyDeviceToHost
- Transfer specified # of bytes from one memory to the other in direction specified

cudaMemcpy(sumHost, sumDev, size, cudaMemcpyDeviceToHost);

Kernel Program for Device

- Set of threads triggered by invocation of a single kernel

- Definition

`__global__ void kernel_fun(argument_list)`

Kernel that can be called from a host function

- Invocation

cf. __device__ for a function called only from device

`kernel_fun <<<execution configuration>>> (operands)`

- Range specifies set of values for thread grid

```
host_fun() {  
    ...  
    dim3 dimGrid(4,2,1)  
    dim3 dimBlock(2,2,2)  
    kernel_fun <<<dimGrid, dimBlock>>> (operands)  
    ...  
}
```

4×2 grid (3rd dimension not used)

2×2×2 block

cf. omp_set_num_threads()

3-element struct accessed by `dimGrid.x`, `dimGrid.y`, `dimGrid.z`

Built-in Variables

- `dim3 gridDim;`

Dimensions of the grid in blocks (gridDim.z unused)

- `dim3 blockDim;`

Dimensions of the block in threads

cf. vproc[3] & vthrd[3] in hmd.c

- `dim3 blockIdx;`

Block index within the grid

- `dim3 threadIdx;`

Thread index within the block

cf. vid[3] & vtd[3] in hmd.c

Calculate Pi with CUDA: pi.cu (1)

```
// Using CUDA device to calculate pi
#include <stdio.h>
#include <cuda.h>

#define NBIN 10000000 // Number of bins
#define NUM_BLOCK 13 // Number of thread blocks
#define NUM_THREAD 192 // Number of threads per block
int tid;
float pi = 0;

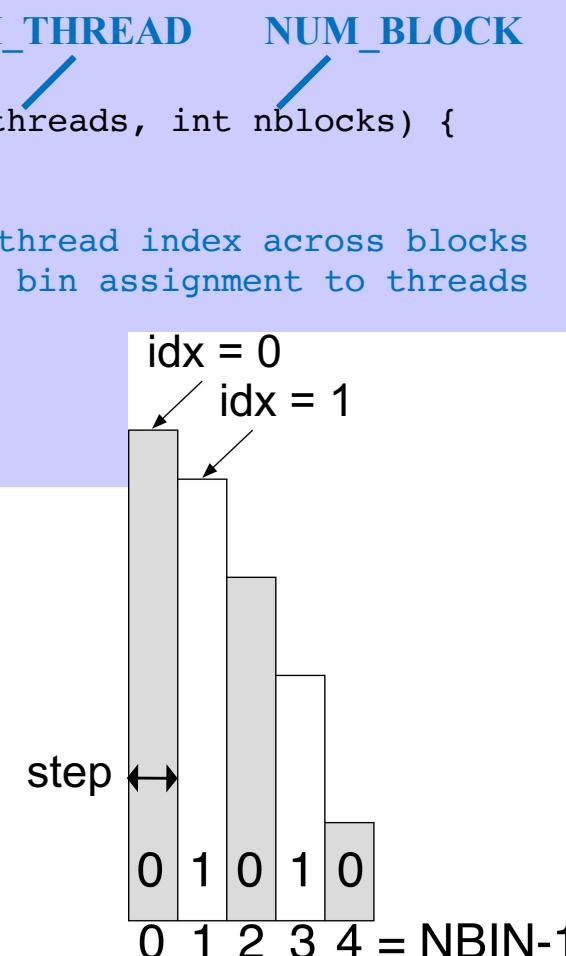

// Kernel that executes on the CUDA device
__global__ void cal_pi(float *sum, int nbin, float step, int nthreads, int nblocks) {
    int i;
    float x;
    int idx = blockIdx.x*blockDim.x+threadIdx.x; // Sequential thread index across blocks
    for (i=idx; i< nbin; i+=nthreads*nblocks) { // Interleaved bin assignment to threads
        x = (i+0.5)*step;
        sum[idx] += 4.0/(1.0+x*x); // Data privatization
    }
}
```

blockIdx.x:	0	1	2
threadIdx.x:	0 1 2 ... 191	0 ... 191	0 ...
idx:	0 1 2 ... 191	192 ... 383	384 ...

1D grid & block

gridDim.x|y = 13|1
blockDim.x|y|z = 192|1|1

Total number of threads = $13 \times 192 = 2,496$

Calculate Pi with CUDA: pi.cu (2)

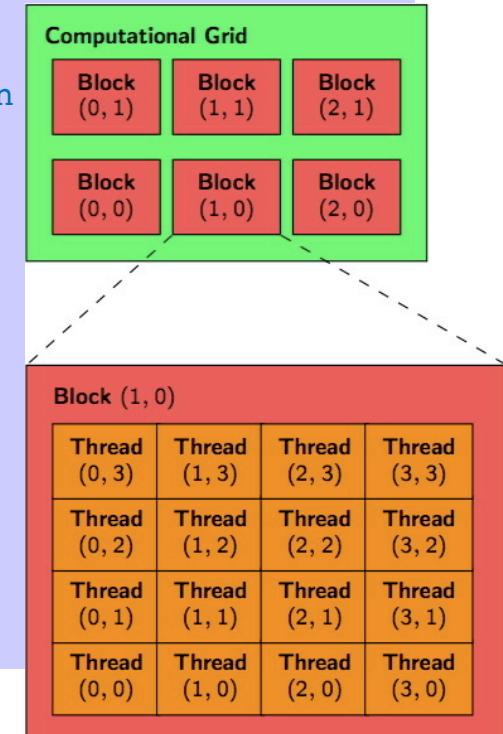

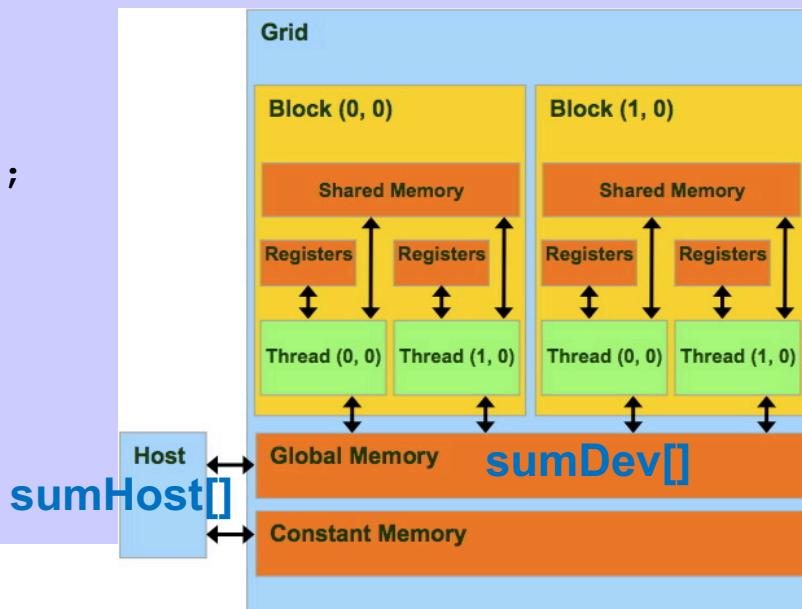

```
// Main routine that executes on the host
int main(void) {    13      192
    dim3 dimGrid(NUM_BLOCK,1,1); // Grid dimensions
    dim3 dimBlock(NUM_THREAD,1,1); // Block dimensions
    float *sumHost, *sumDev; // Pointer to host & device arrays

    float step = 1.0/NBIN; // Step size
    size_t size = NUM_BLOCK*NUM_THREAD*sizeof(float); // Array memory size
    sumHost = (float *)malloc(size); // Allocate array on host
    cudaMalloc((void **) &sumDev, size); // Allocate array on device
    // Initialize array in device to 0
    cudaMemset(sumDev, 0, size);
    // Do calculation on device by calling CUDA kernel
    cal_pi <<<dimGrid, dimBlock>>> (sumDev, NBIN, step, NUM_THREAD, NUM_BLOCK);
    // Retrieve result from device and store it in host array
    cudaMemcpy(sumHost, sumDev, size, cudaMemcpyDeviceToHost);
    for(tid=0; tid<NUM_THREAD*NUM_BLOCK; tid++) // Thread reduction
        pi += sumHost[tid];
    pi *= step;

    // Print results
    printf("PI = %f\n",pi);

    // Cleanup
    free(sumHost);
    cudaFree(sumDev);

    return 0;
}
```

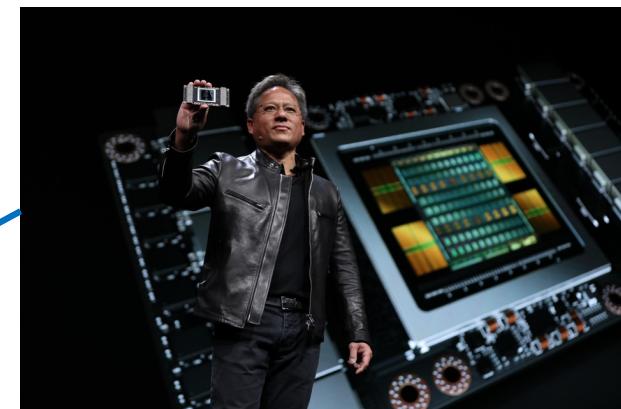

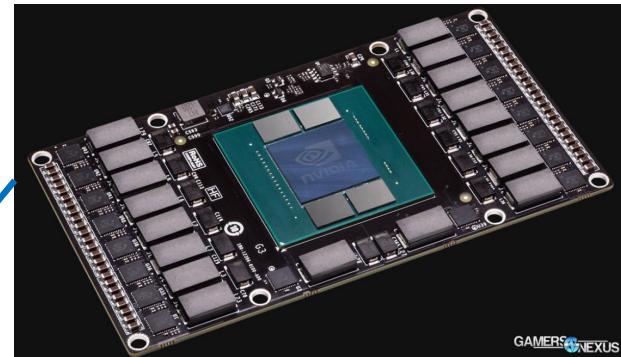

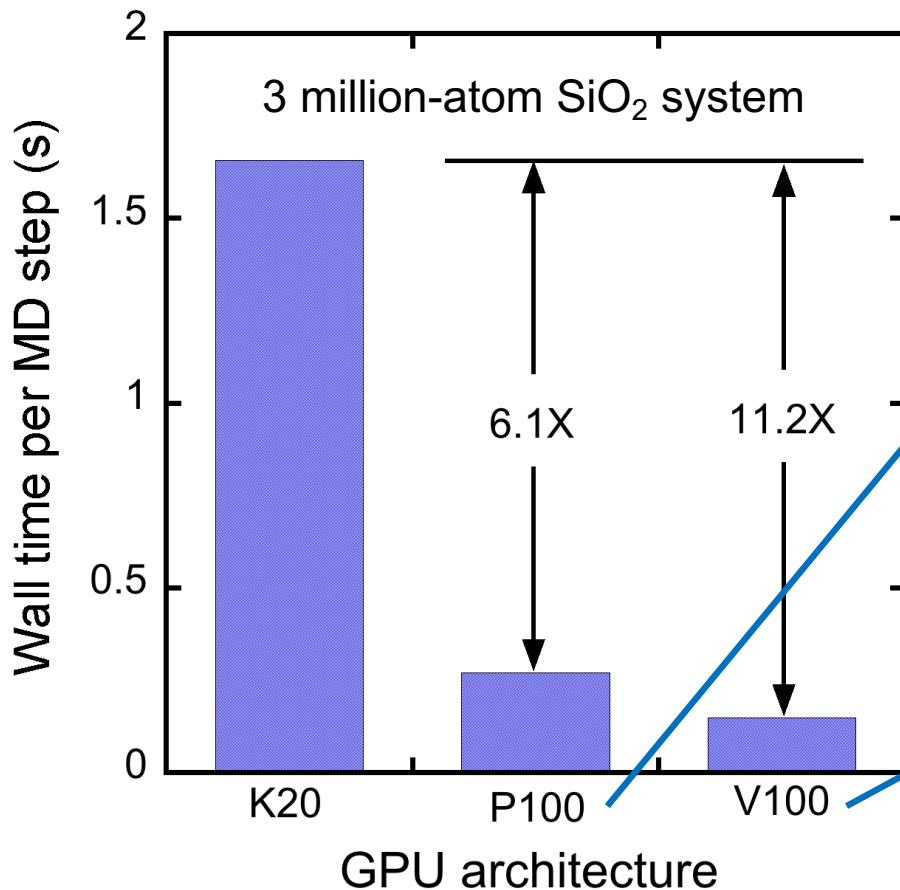

Summary: CUDA Computing

- * Single program multiple data we have learned is called **single instruction multiple threads (SIMT)** in GPU terminology

New Generations of GPUs

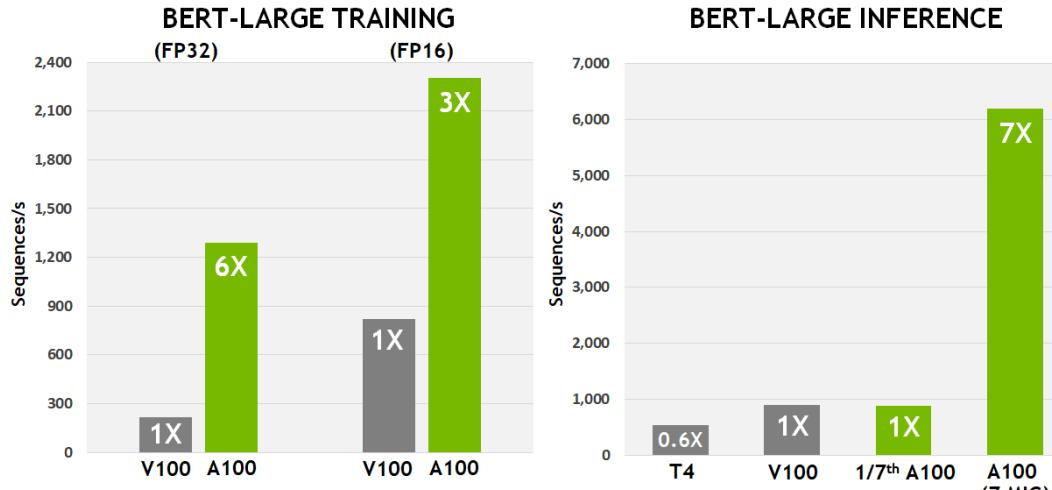

- Running time per molecular dynamics (MD) step on Kepler (K20), Pascal (P100) & Volta (V100) GPUs

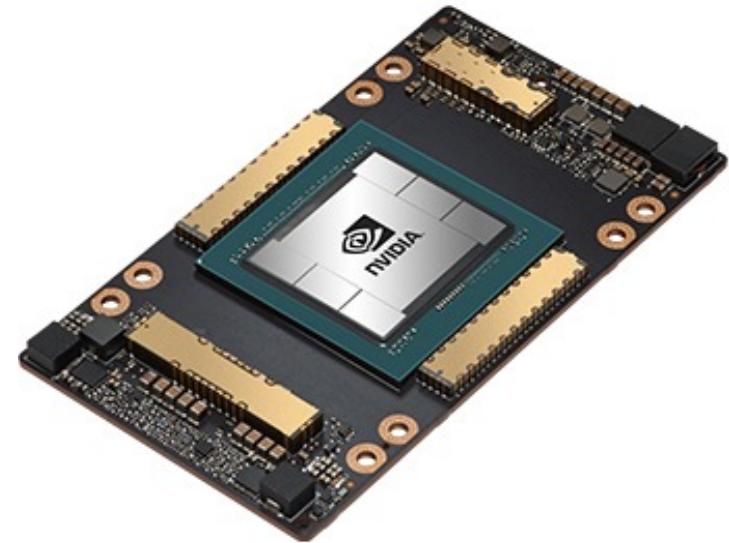

New Generations of GPUs (2)

- A100 is at CARC

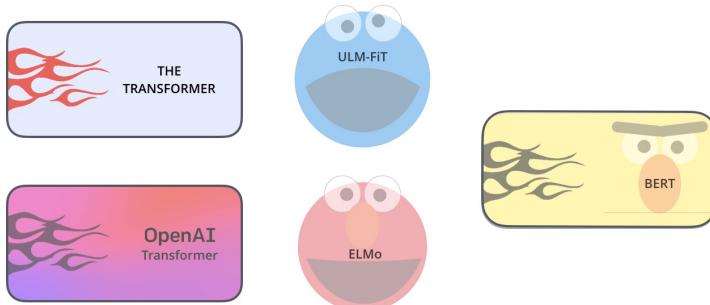

UNIFIED AI ACCELERATION

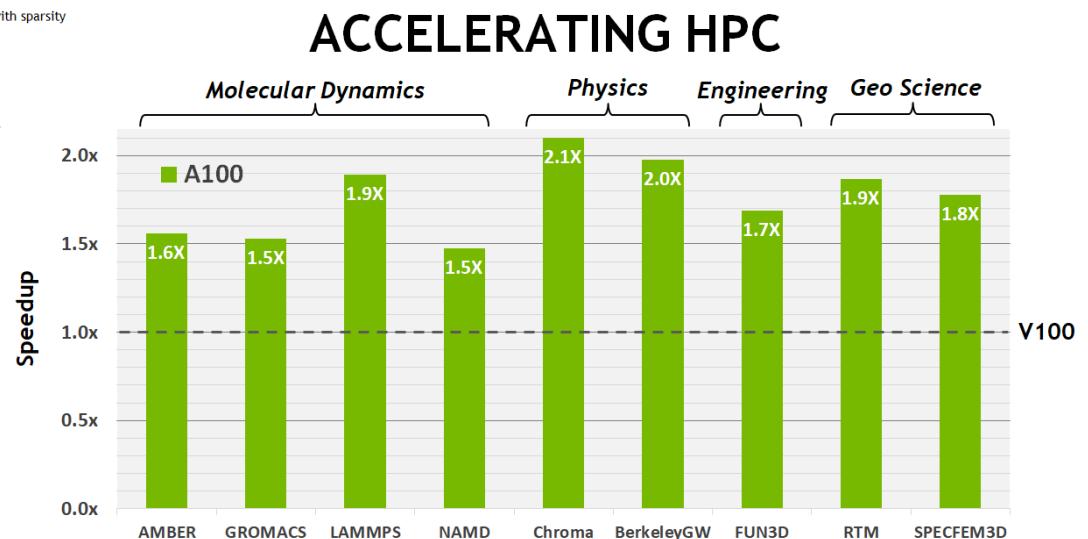

All results are measured.
BERT Large Training (FP32 & FP16) measures Pre-Training phase, uses PyTorch including (2/3) Phase1 with Seq Len 128 and (1/3) Phase 2 with Seq Len 512,
V100 is DGX1 Server with 8xV100, A100 is DGX A100 Server with 8xA100, A100 uses TF32 Tensor Core for FP32 training
BERT Large Inference uses TRT7.1 for T4/V100, with INT8/FP16 at batch size 256. Pre-production TRT for A100, uses batch size 94 and INT8 with sparsity

BERT: Bidirectional Encoder Representations from Transformers used in natural language processing (NLP)

cf. [Pytorch GPU engine](#)

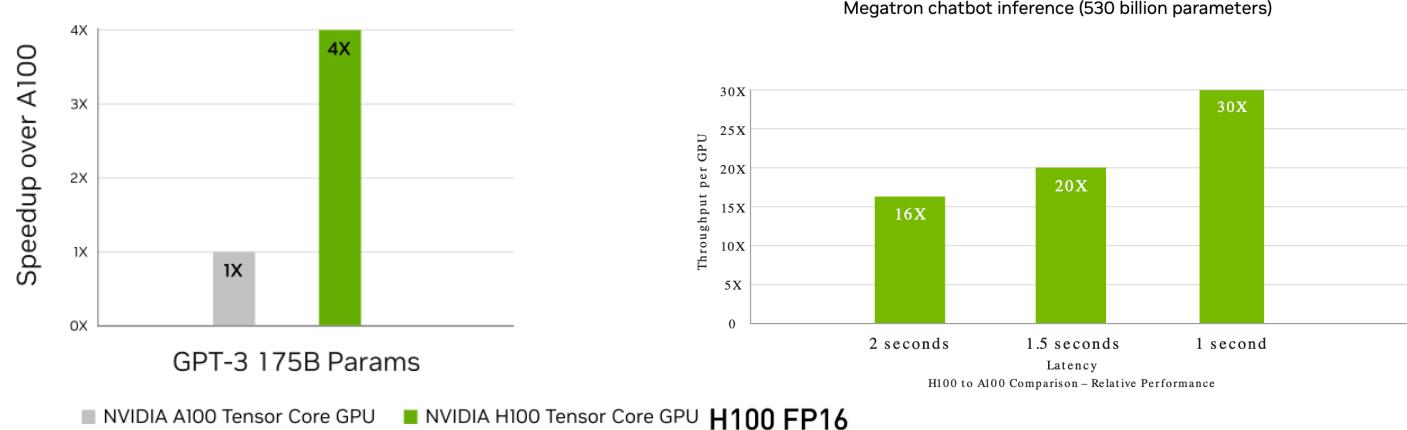

All results are measured.
Except BerkeleyGW, V100 used is single V100 SXM2, A100 used is single A100 SXM4
More apps detail: AMBER based on PME-Cellulose, GROMACS with STMV (h-bond), LAMMPS with Atomic Fluid LJ-2,5, NAMD with v3.0a1 STMV_NVE
Chroma with szsc01_24_128, FUN3D with dpw, RTM with isotropic Radius 4 1024^3, SPECFEM3D with Cartesian four material model
BerkeleyGW based on Chi Sum and uses 8xV100 in DGX-1, vs 8xA100 in DGX A100

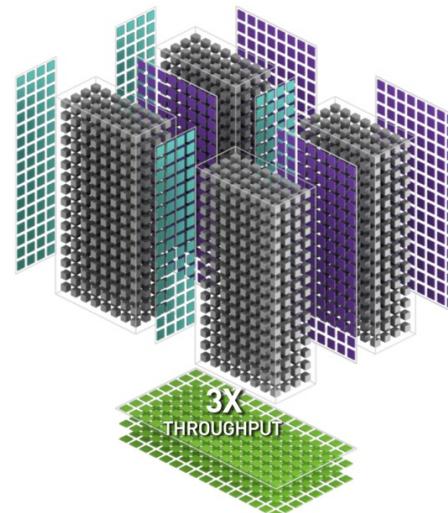

New Generations of GPUs (3)

- H100 is faster: 14,592 CUDA cores & 456 tensor cores

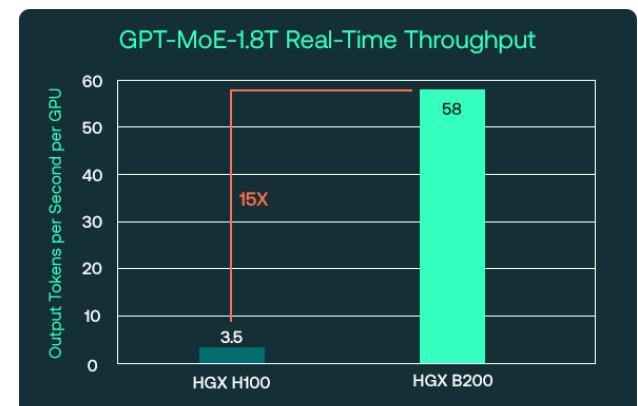

Up to 30X higher AI inference performance on the largest models

- Unlike general-purpose CUDA cores, tensor cores are specialized processing units designed for (mixed-precision) matrix operations in deep learning

- Now B200:
16,896 CUDA cores & 528 tensor cores

New: NERSC NESAP Award

- NERSC (National Energy Research Scientific Computing Center) Science Acceleration Program (NESAP) Award (2025-2028)

T. Linker–PI, V. Mariana (SLAC); K. Nomura, A. Nakano (USC)

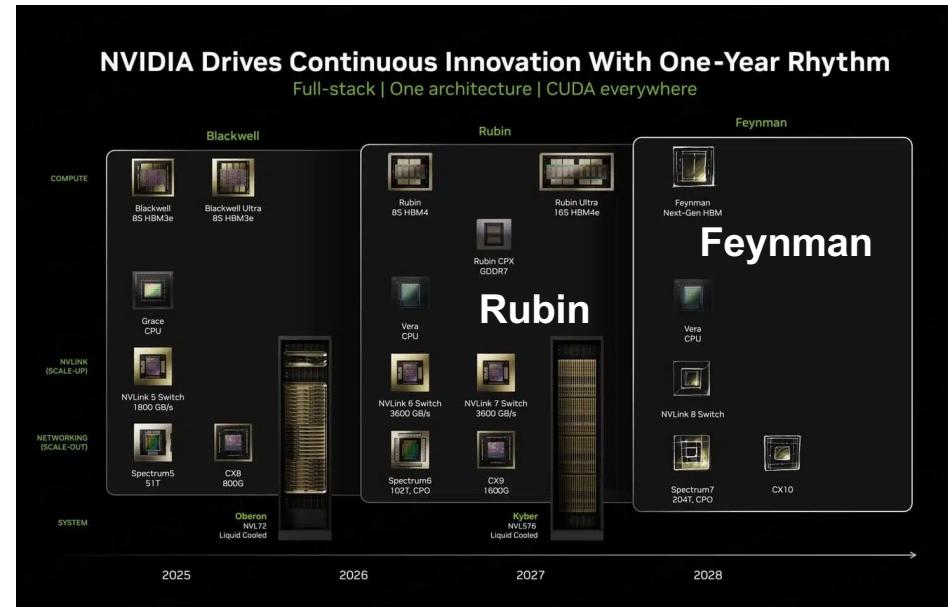

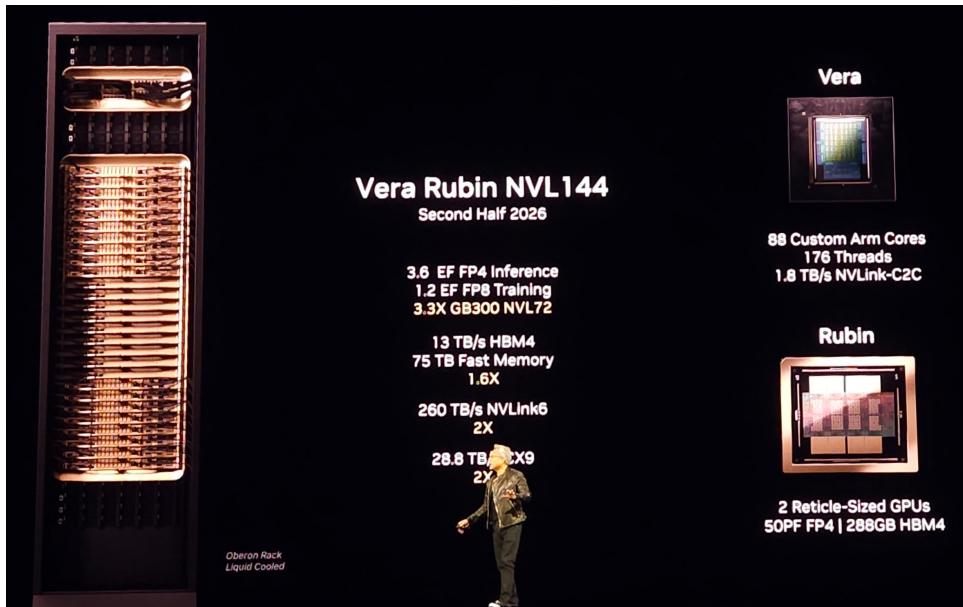

Subject: Your Project has been Selected as a NESAP Broader Engagement Team

Date: October 7, 2025 at 12:56:55 PM PDT

Thank you for applying to NESAP for Doudna*. It is our pleasure to inform you that your project "**Ultrafast RLCAT**" has been selected as one of the NESAP for *Doudna* Tier 2 "Broader Engagement" Teams.

*NVIDIA Vera-Rubin CPU-GPU platform

Warp & Control Divergence

- Threads in a block are subdivided into warps (e.g. consisting of 32 threads)
- Warps are executed in SIMD (single-instruction multiple-data) fashion, *i.e.*, multiple threads concurrently perform the same operation
- CUDA provides warp-level primitives for efficient warp-level programming
- Single instruction multiple thread (SIMT) execution model penalizes control divergence, where different threads execute different instructions
- Warp voting: All threads (e.g. particles) within a warp vote on which computation to perform, with an overhead of unnecessary computations, for example:

if (any thread in a warp wants to compute) all threads do
