Immersive & Interactive Visualization

Challenge: billion-atom walkthrough

Solution: parallel & distributed Atomsviewer

Locality in Data Compression

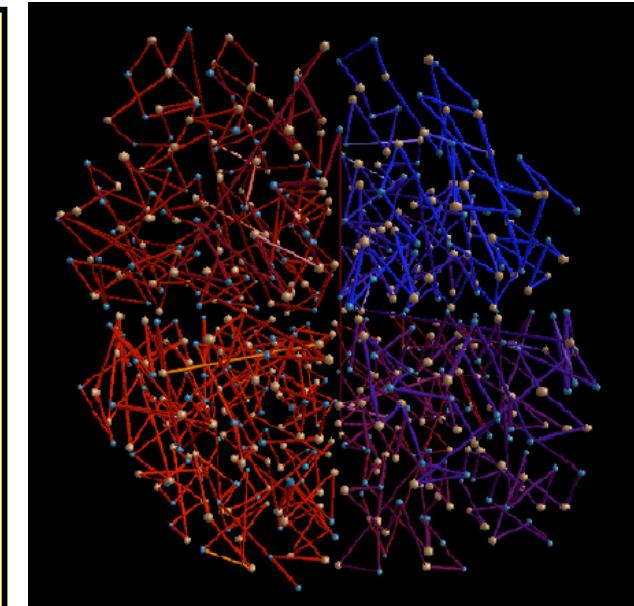

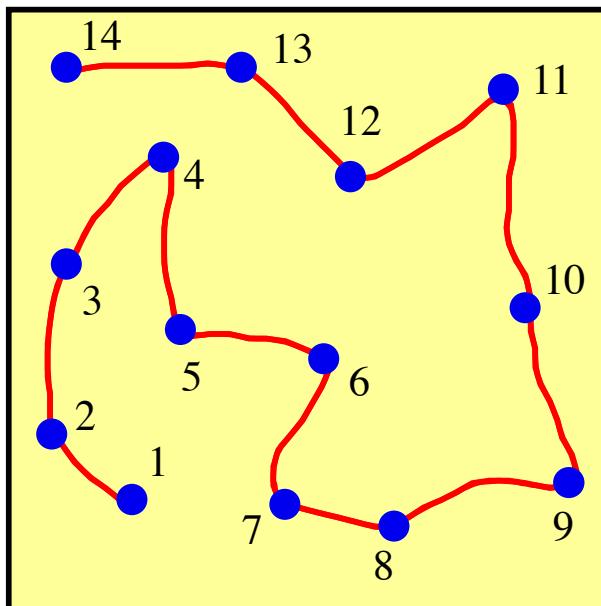

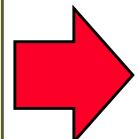

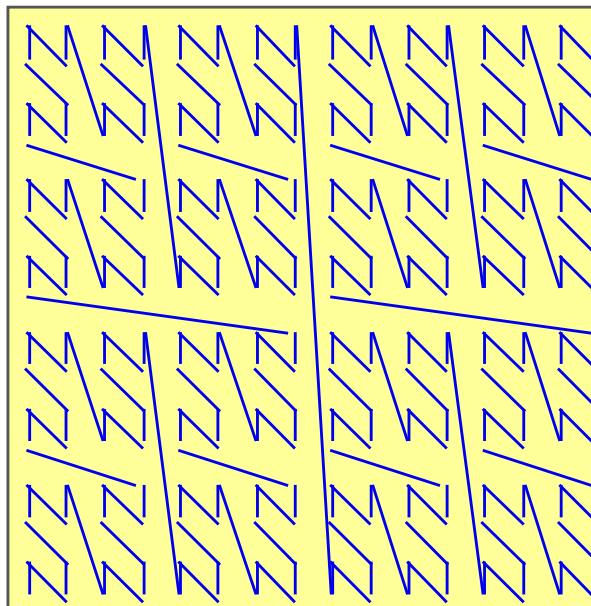

Massive data transfer via wide area network:
75 GB/step of data for 1.5 billion-atom MD!
→ Compressed software pipeline

Scalable encoding:

- Store relative positions on spacefilling curve: $O(N \log N) \rightarrow O(N)$

Result:

- Data size, 50Bytes/atom → 6 Bytes/atom

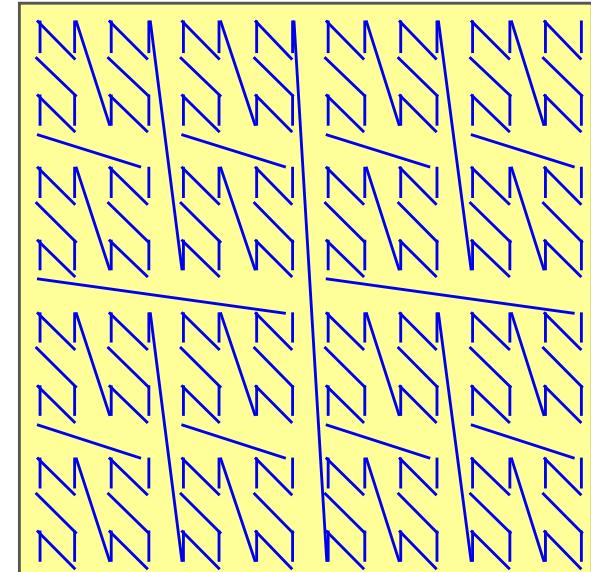

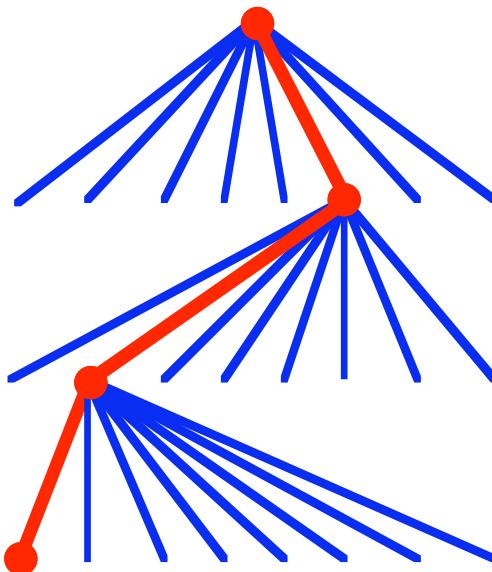

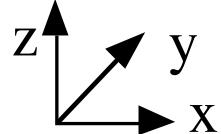

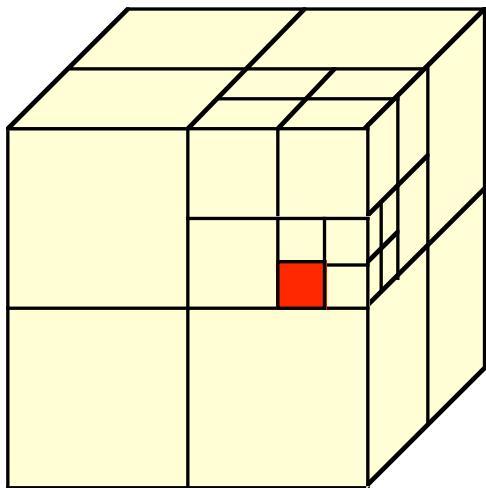

Data Compression for Scalable I/O

**Challenge: Massive data transfer via OC-12 (622 Mbps)
75 GB/frame of data for a 1.5-billion-atom MD!**

Scalable encoding:

- Spacefilling curve based on octree index

x =	1	1	0
y =	0	0	0
z =	1	0	0
R =	101	001	000

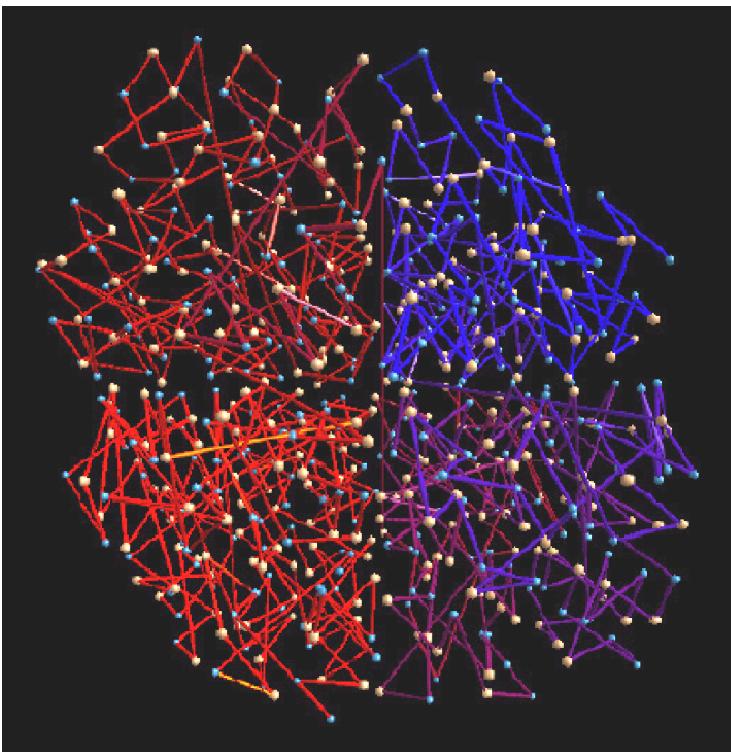

3D → list map preserves spatial proximity

Spacefilling-Curve Data Compression

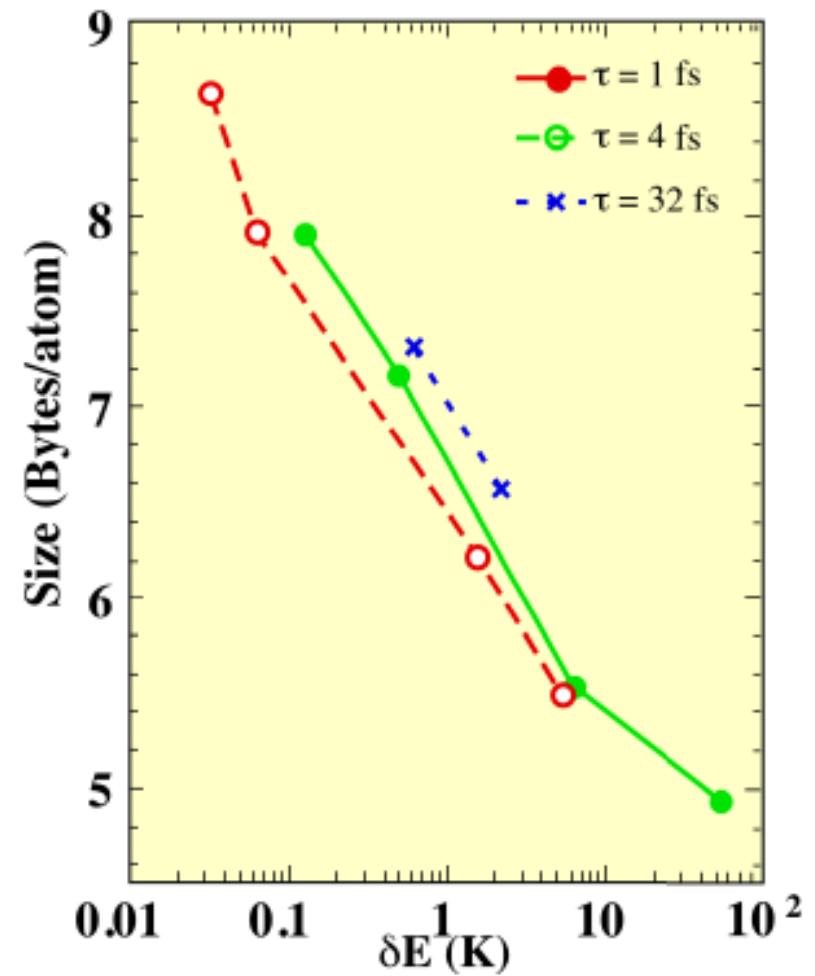

Algorithm:

1. Sort particles along the spacefilling curve
2. Store relative positions: $O(N \log N) \rightarrow O(N)$
 - Adaptive variable-length encoding to handle outliers
 - User-controlled error bound

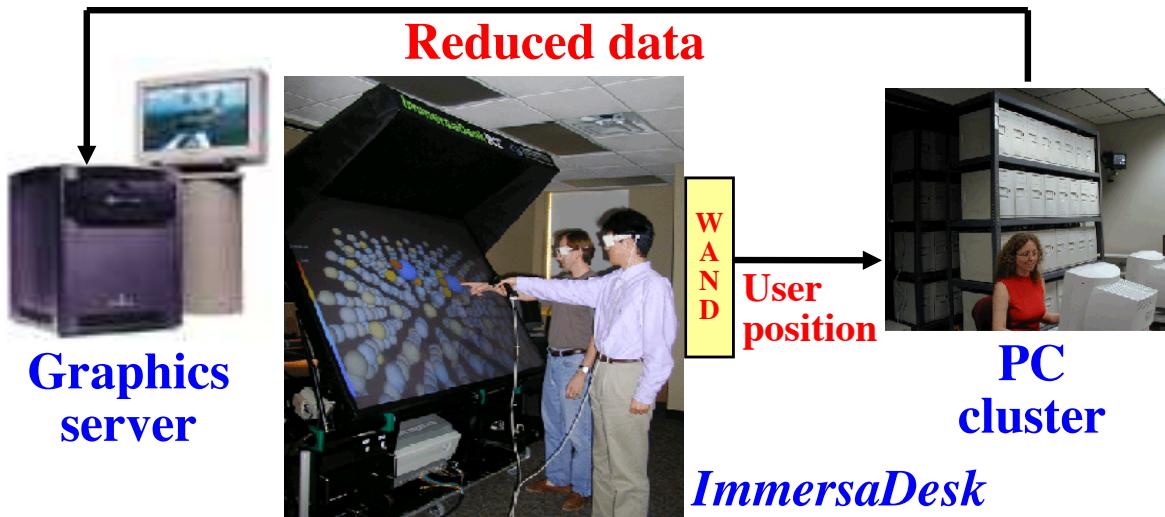

Result:

- An order-of-magnitude reduction of I/O size: $50 \rightarrow 6$ Bytes/atom

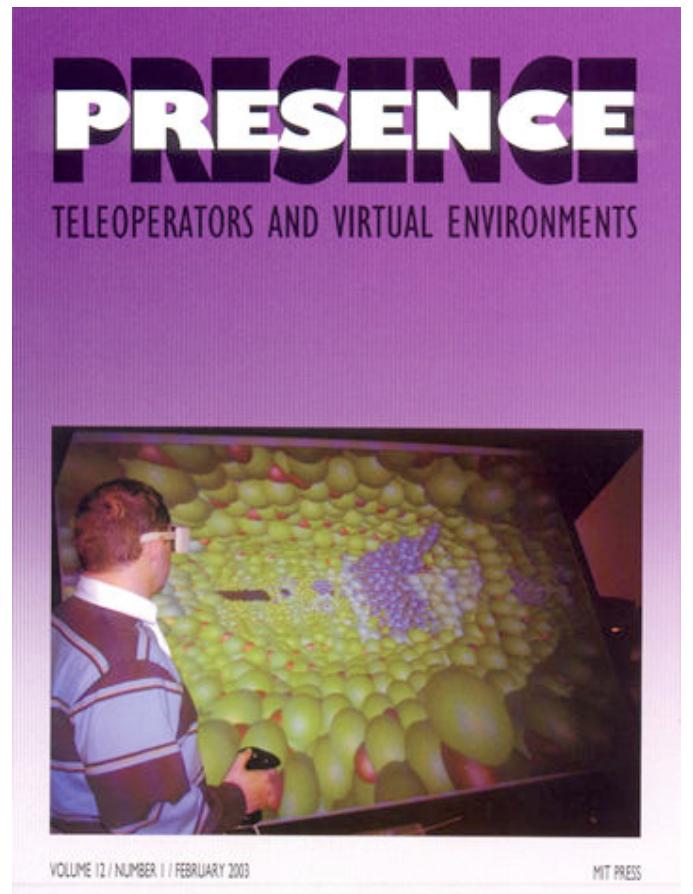

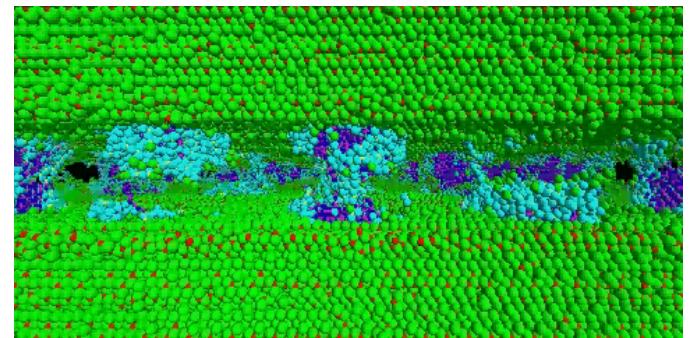

Data Locality in Visualization

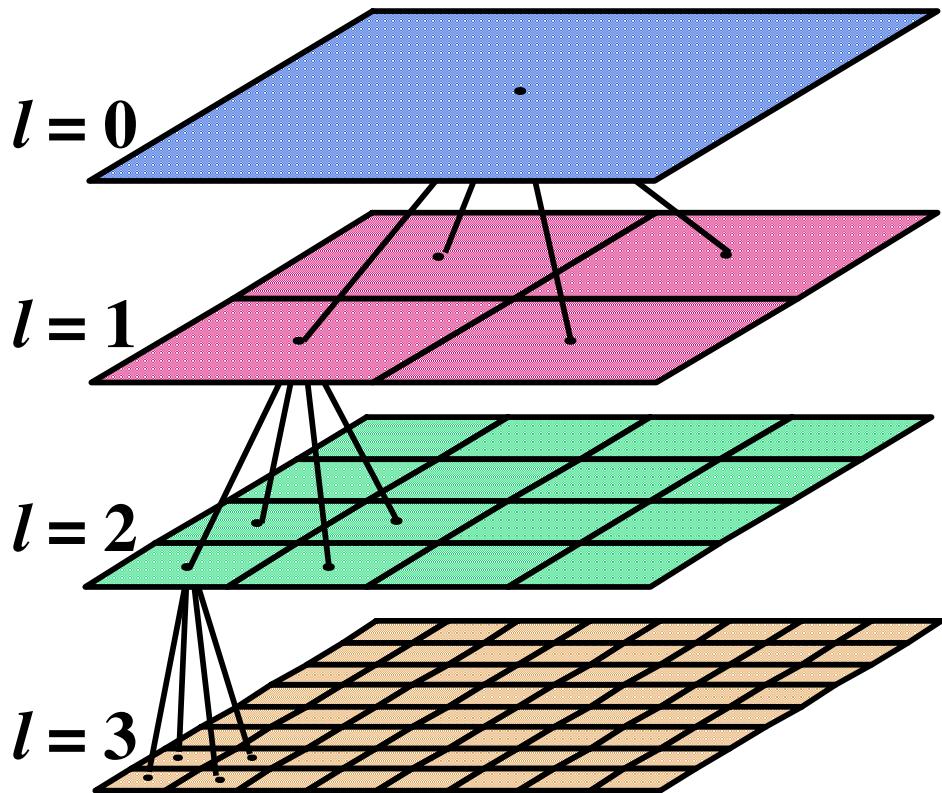

- Octree-based fast view-frustum culling
- Probabilistic occlusion culling
- Parallel/distributed processing

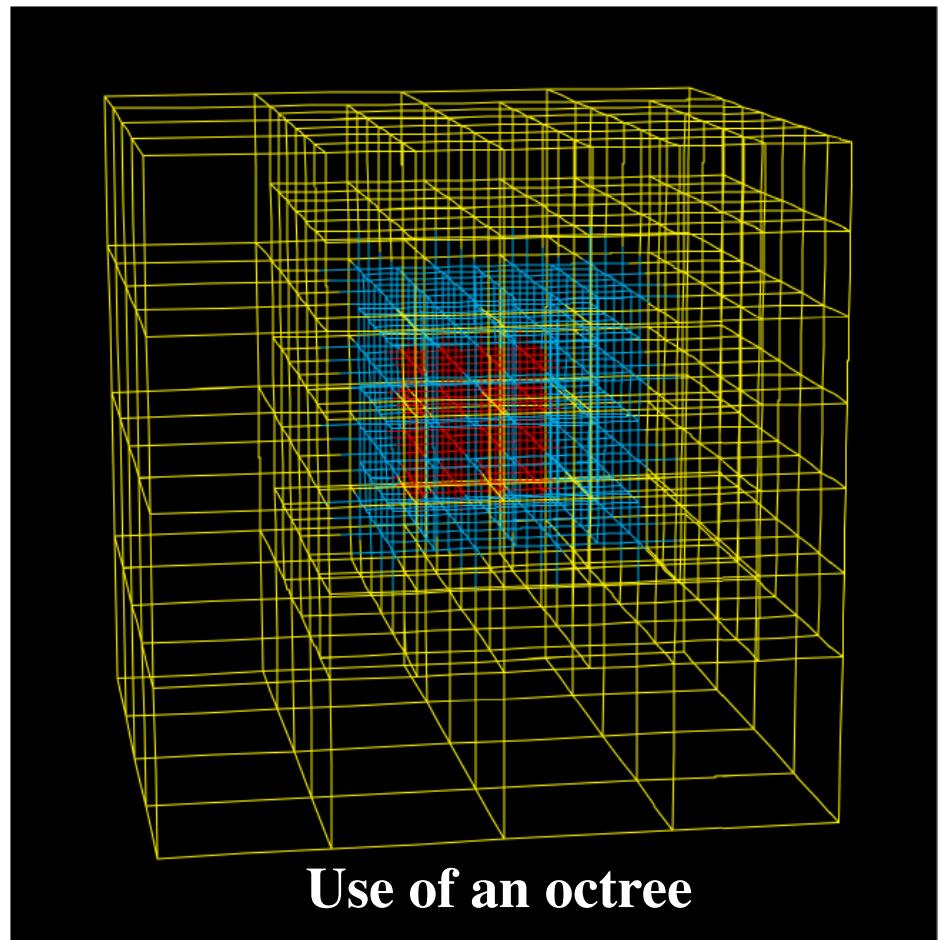

- Interactive visualization of a billion-atom dataset in immersive environment

Hierarchical Abstraction

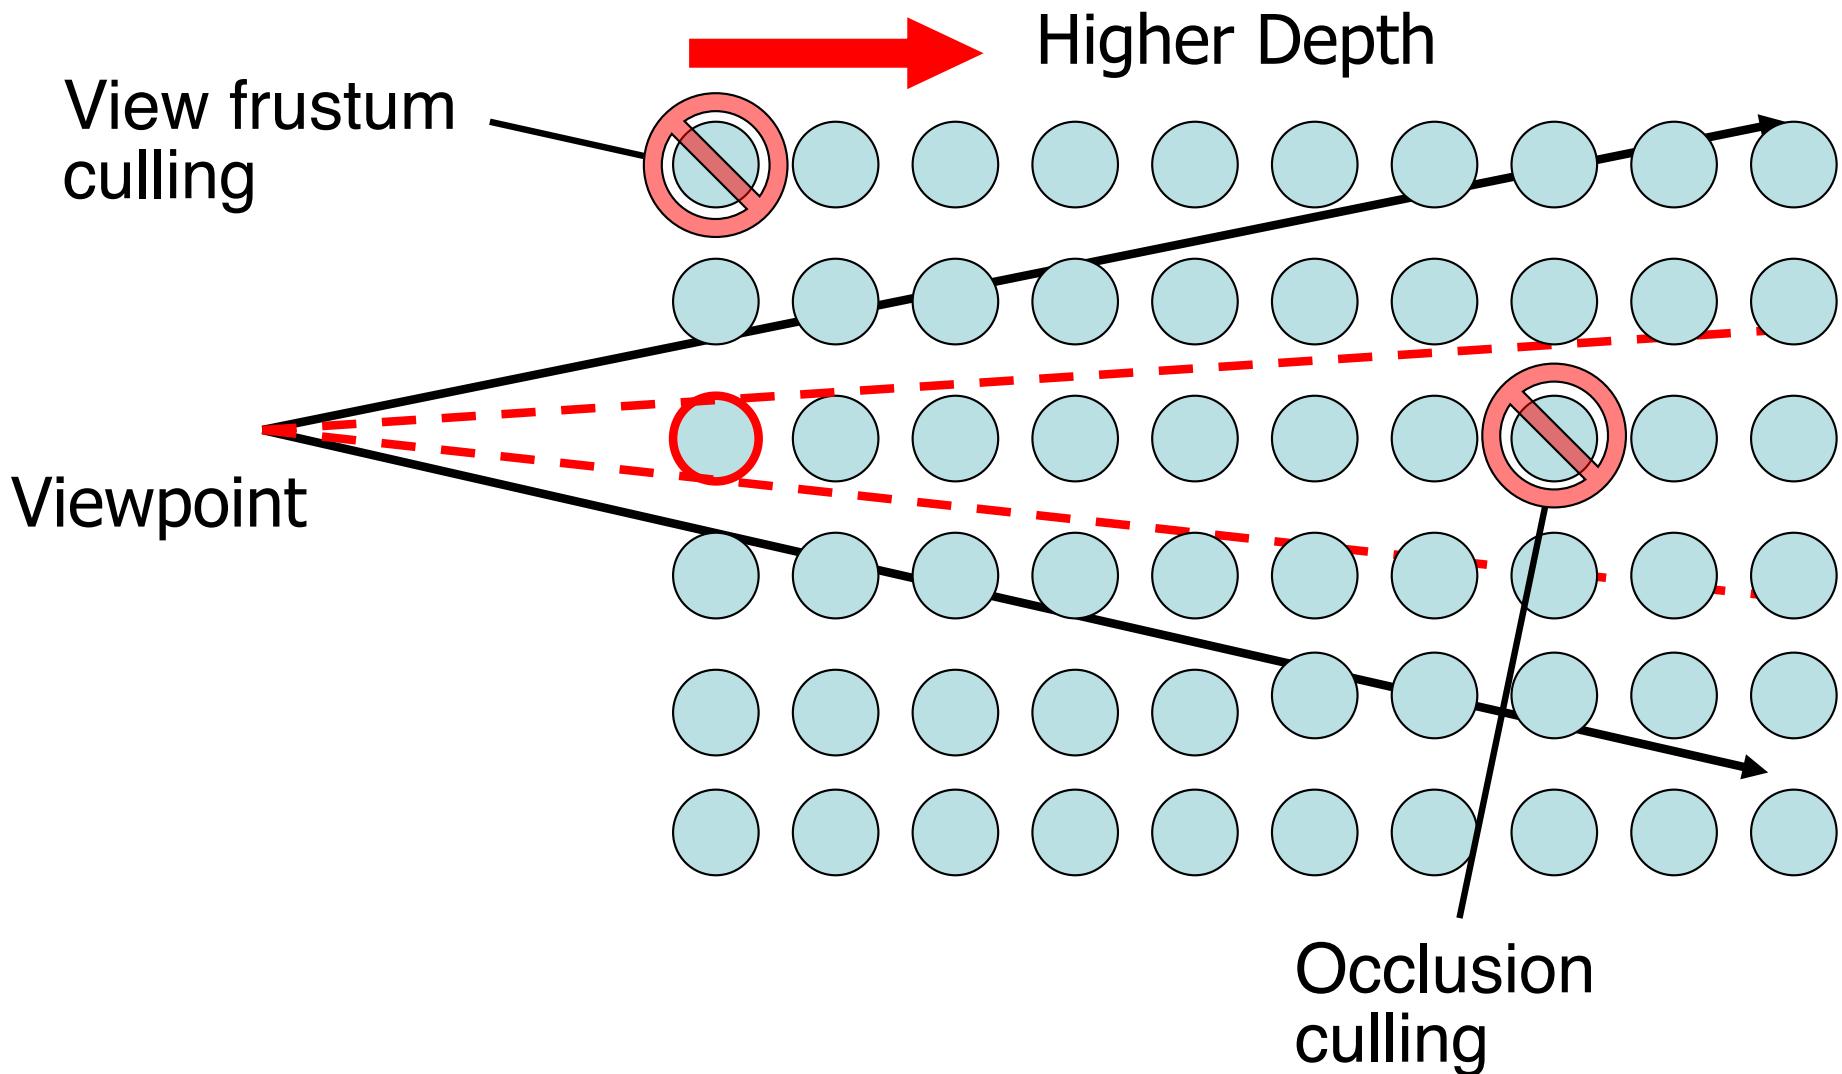

2D example

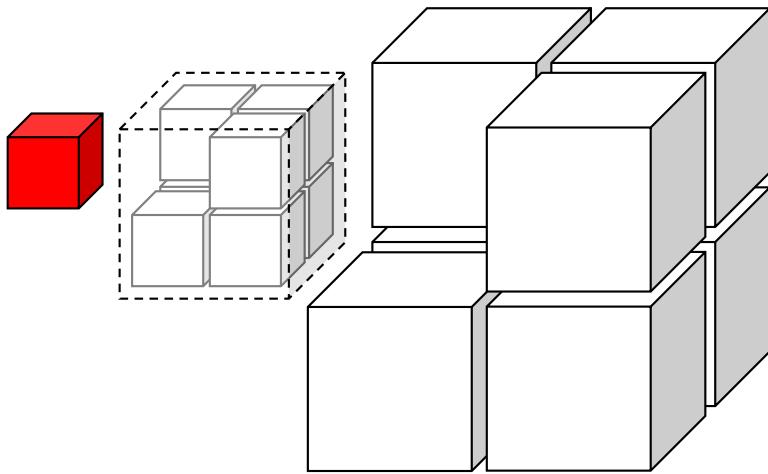

Use of an octree

- Larger clusters for longer distances
- Recursively subdivide the 3D space to form an octree

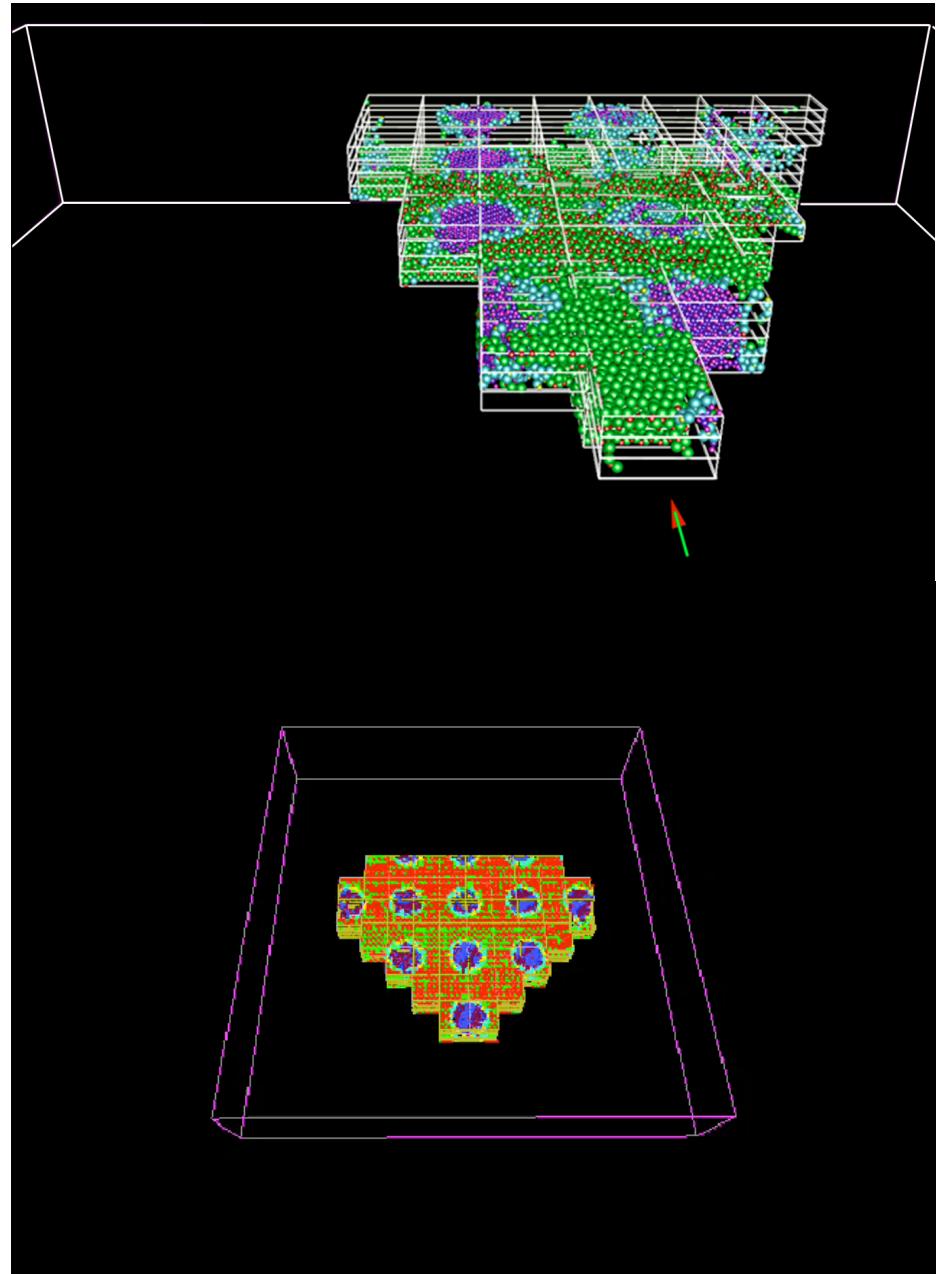

Visibility Culling

Octree-based View-Frustum Culling

- Use the octree data structure to efficiently select only visible atoms
- Complexity
Insertion into octree: $O(N)$
Data extraction: $O(\log N)$

Probabilistic Occlusion Culling

- Remove atoms that are occluded by other atoms closer to the viewer
- Regions farther away from the viewer is more likely to be occluded than one in front of the viewer

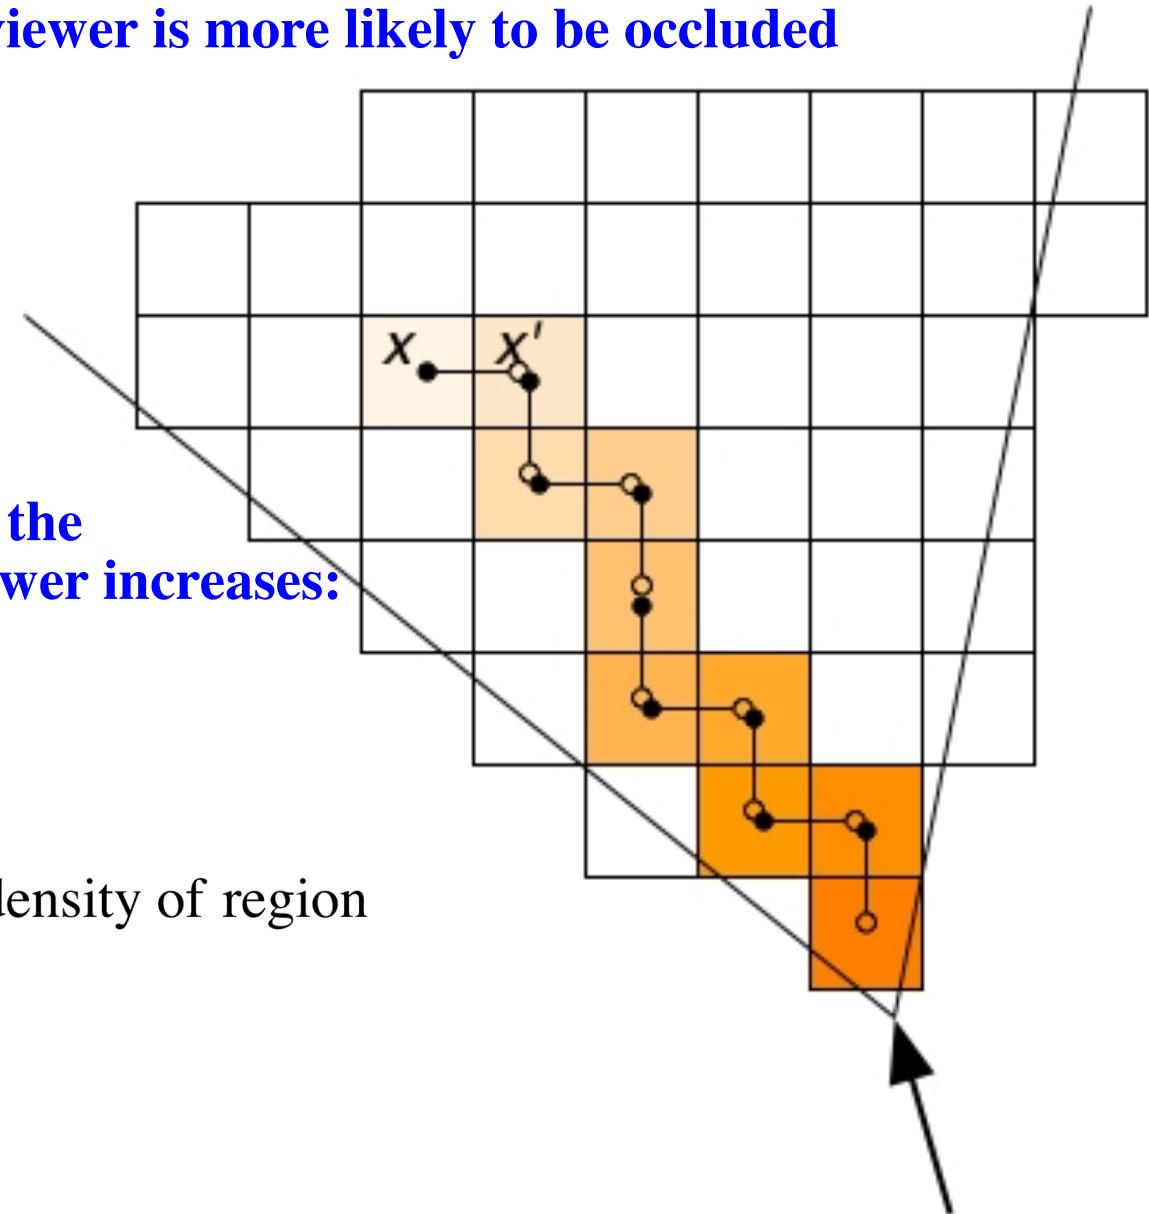

- Draw fewer atoms per region as the distance of a region from the viewer increases:
visibility value $v(x)$ for region x

- Recurrence along the view line

$$v_x = \begin{cases} 1 & x = 0 \\ f(D_{x'}, v_{x'}) & \text{else} \end{cases} \quad D_x = \text{density of region}$$

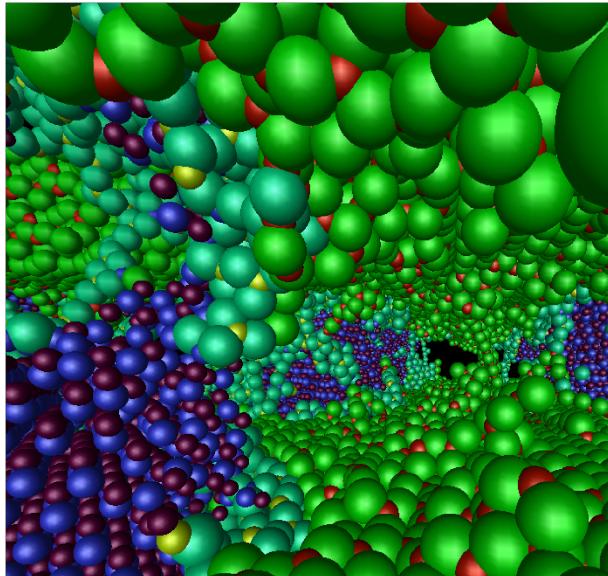

- Run time adaptation

$$v'_x = f(\text{user speed}) \times v_x$$

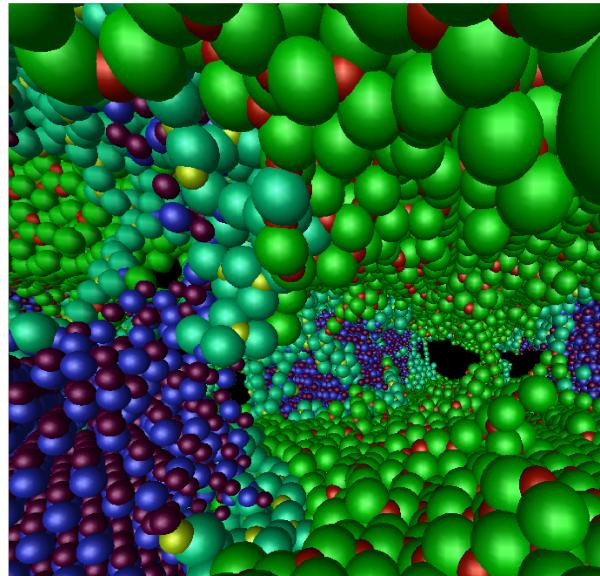

Results of Probabilistic Occlusion Culling

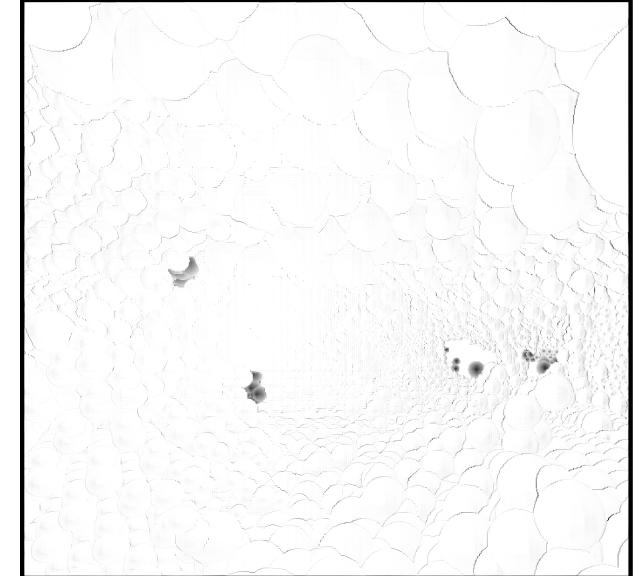

Original

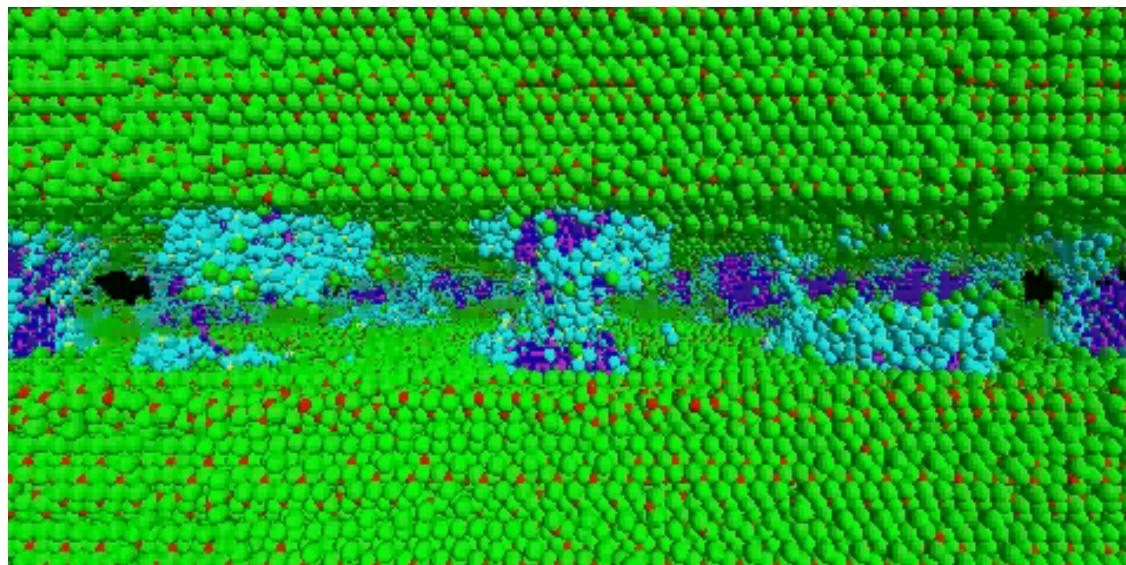

Probabilistic

Difference

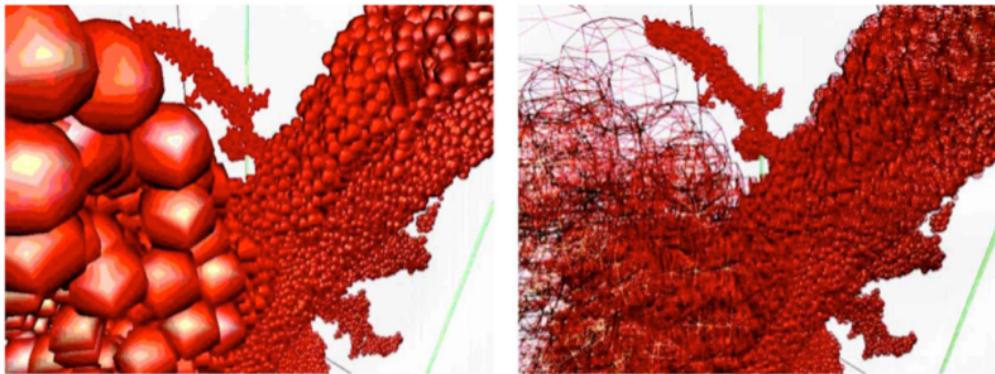

68% fewer objects; 3 \times frame rate

Multiresolution Culling & Rendering

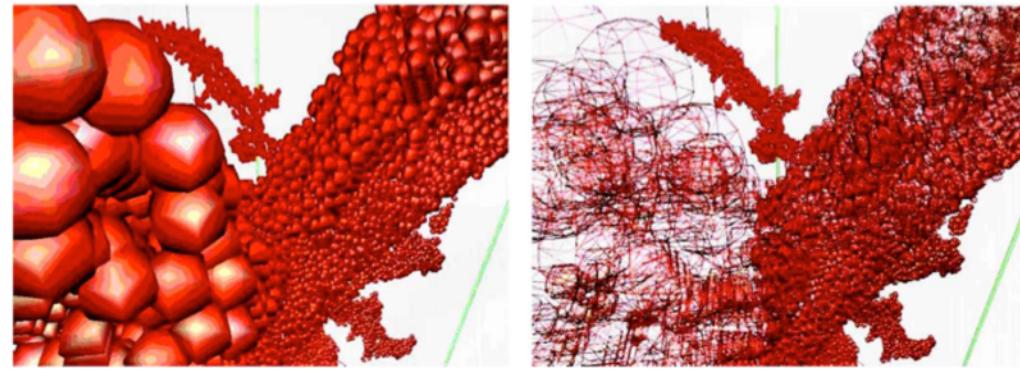

- Per-octree node operations:
 - Frustum culling
 - Probabilistic occlusion culling
- Per-atom operations
 - Multiple levels-of-detail
 - Occlusion culling (per-object, per-octree node)

Without multiresolution

.94fps - 90,000 particles

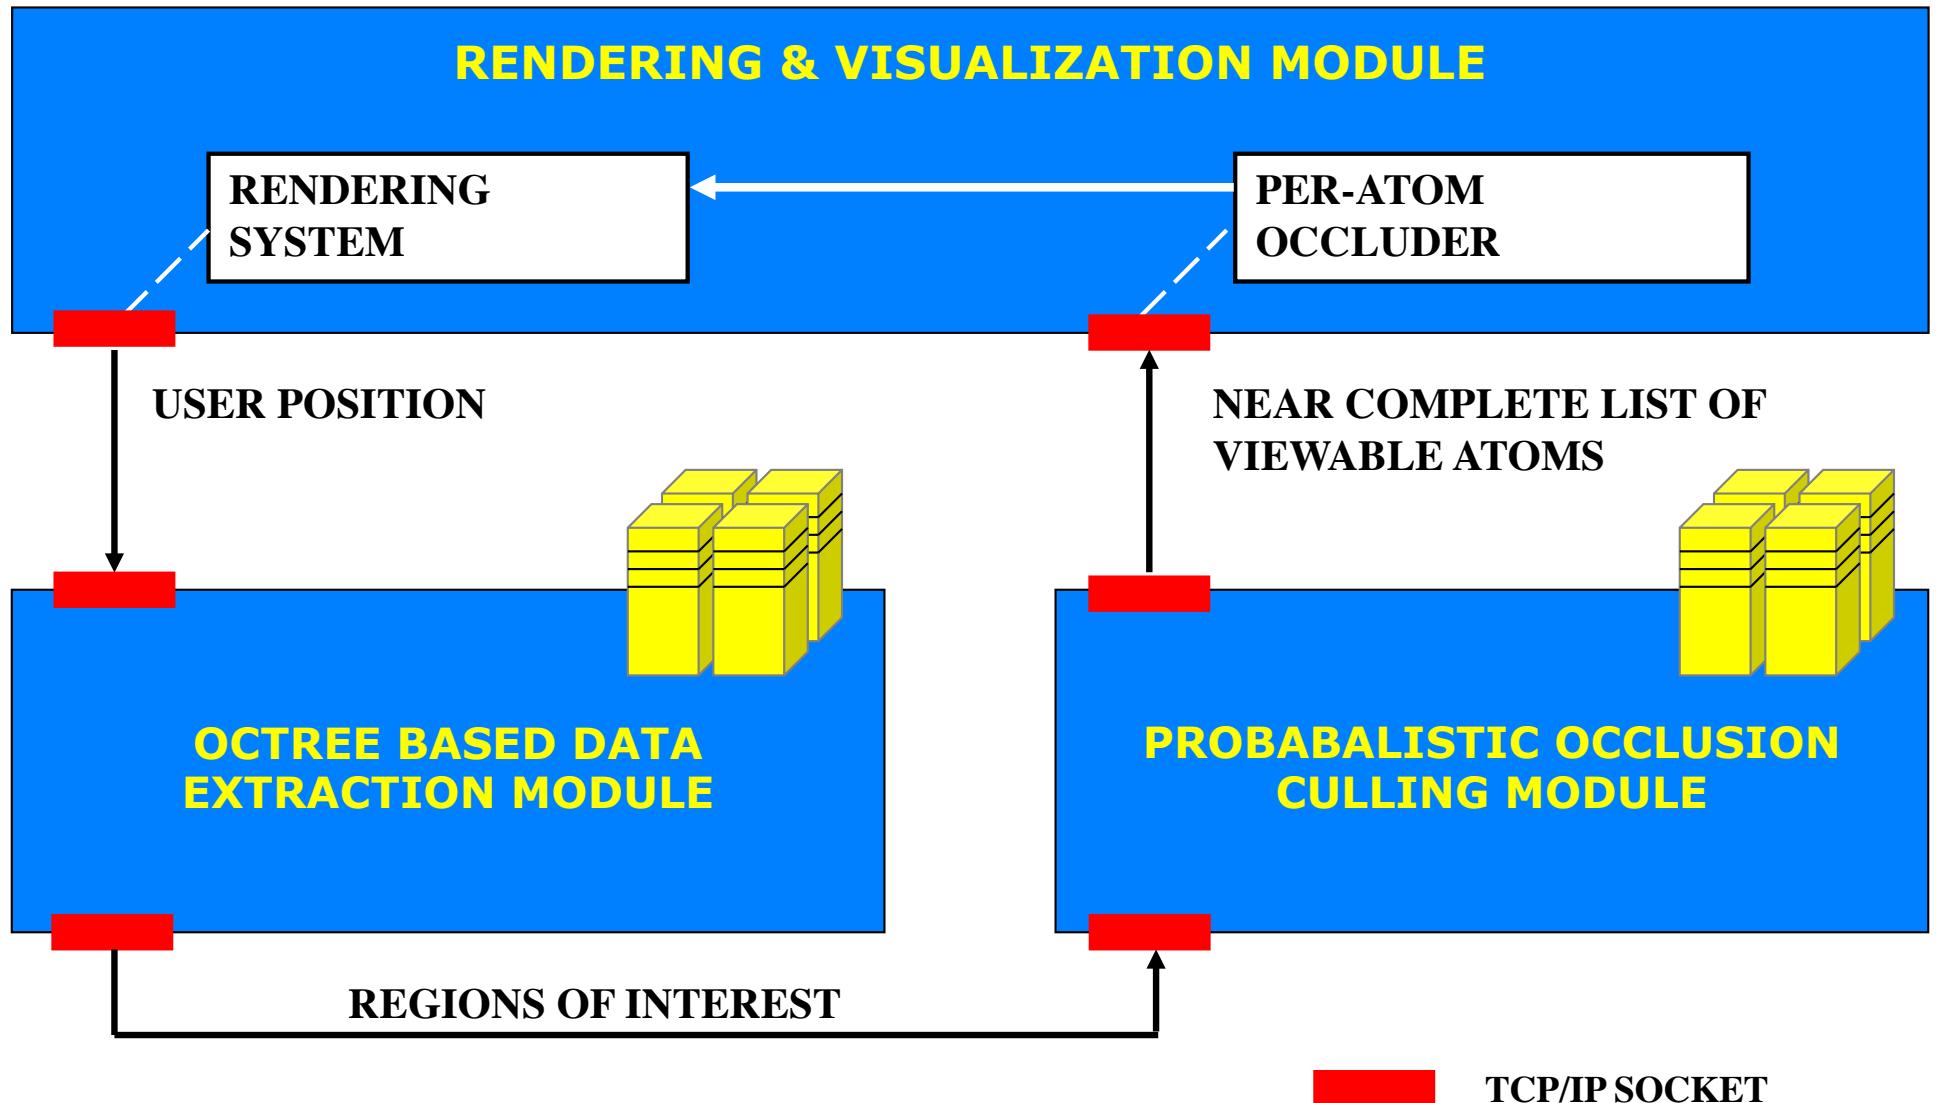

With multiresolution

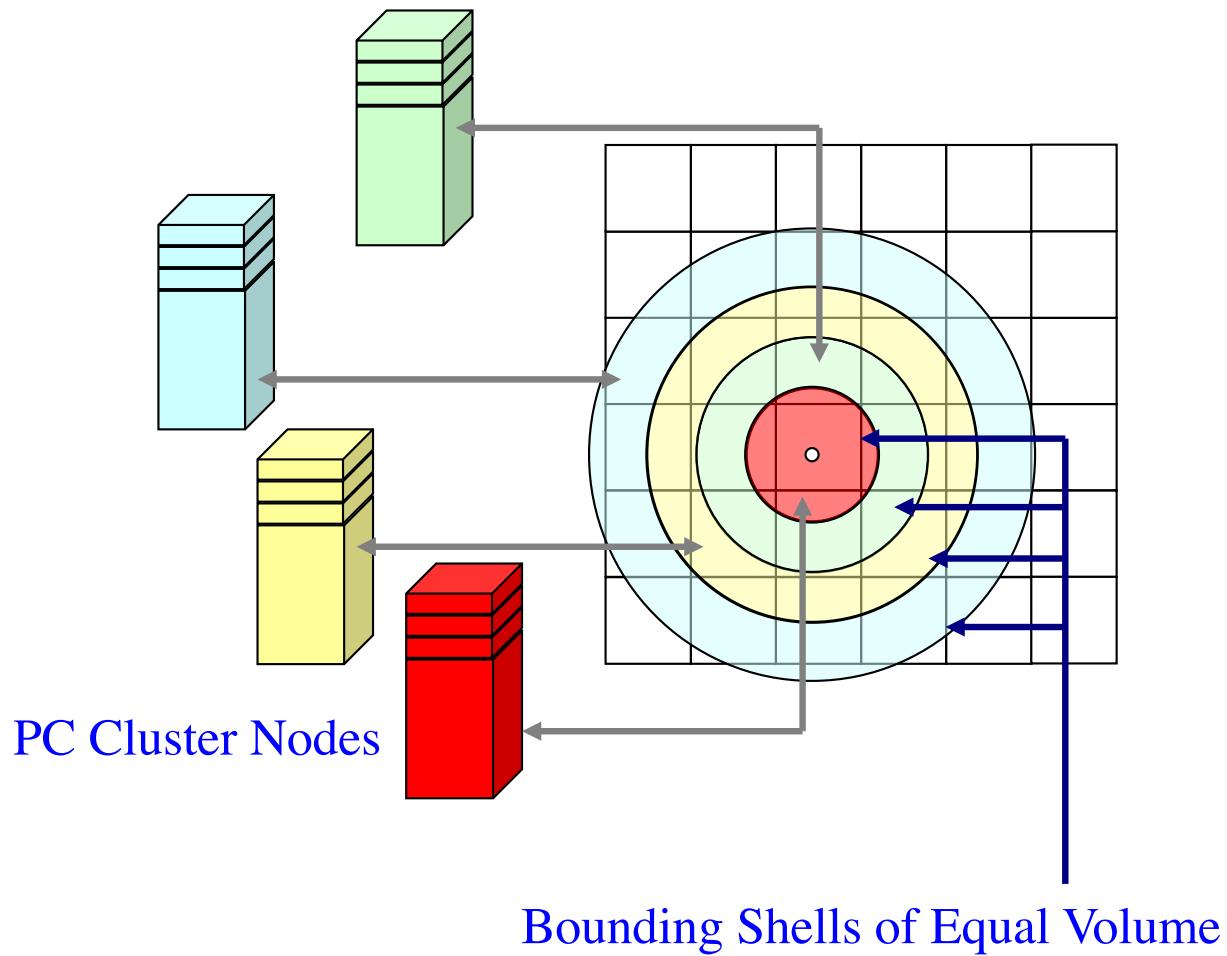

3.2fps - 4,500 particles

Outflow pathways of optic nerves from the retina of a rabbit eye
(Experimental data by C. Burgoyne & R. Beuerman, *LSU Eye Center*)

Distributed Architecture

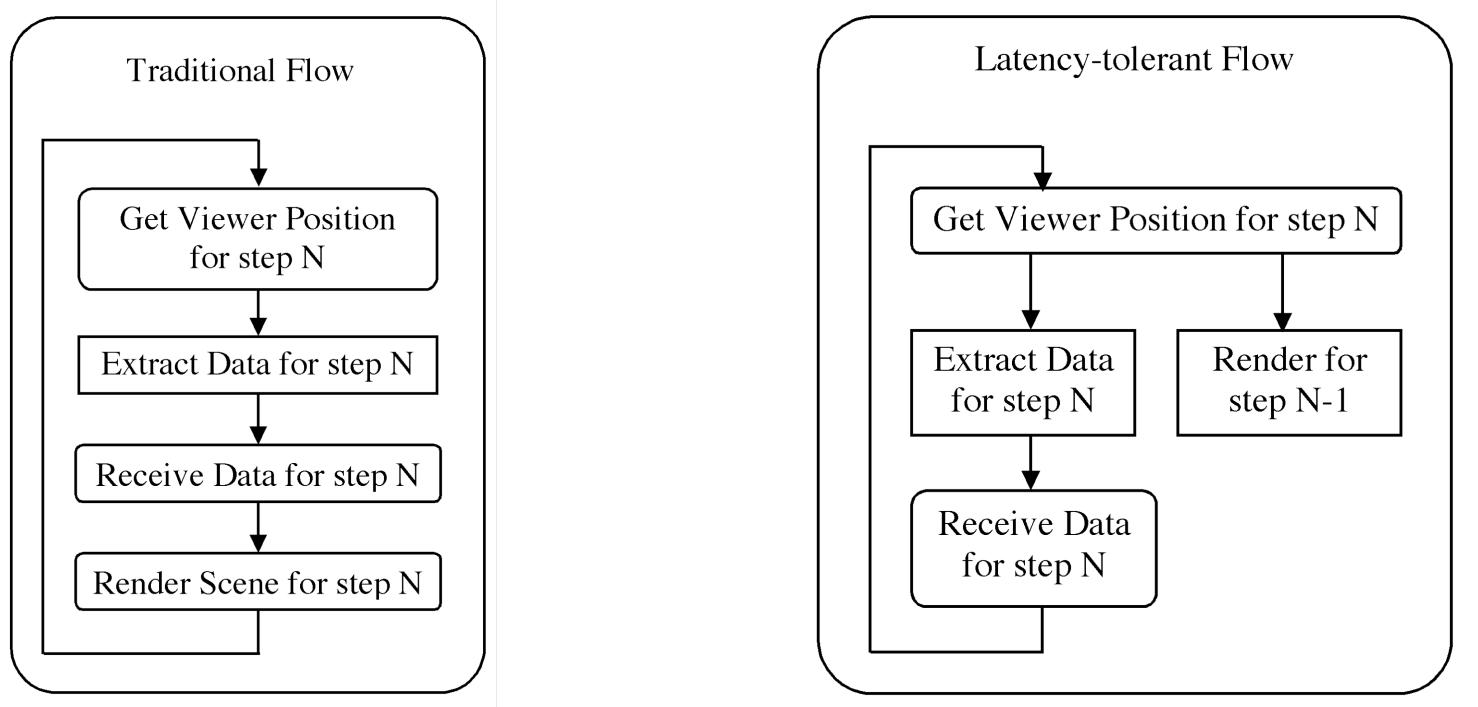

Parallel Octree Extraction

- Individual copies of the octree with each node
- Spherical extraction by the use of shells of equal volume
- Load balancing due to the equal use of each processor for extraction

Latency Hiding

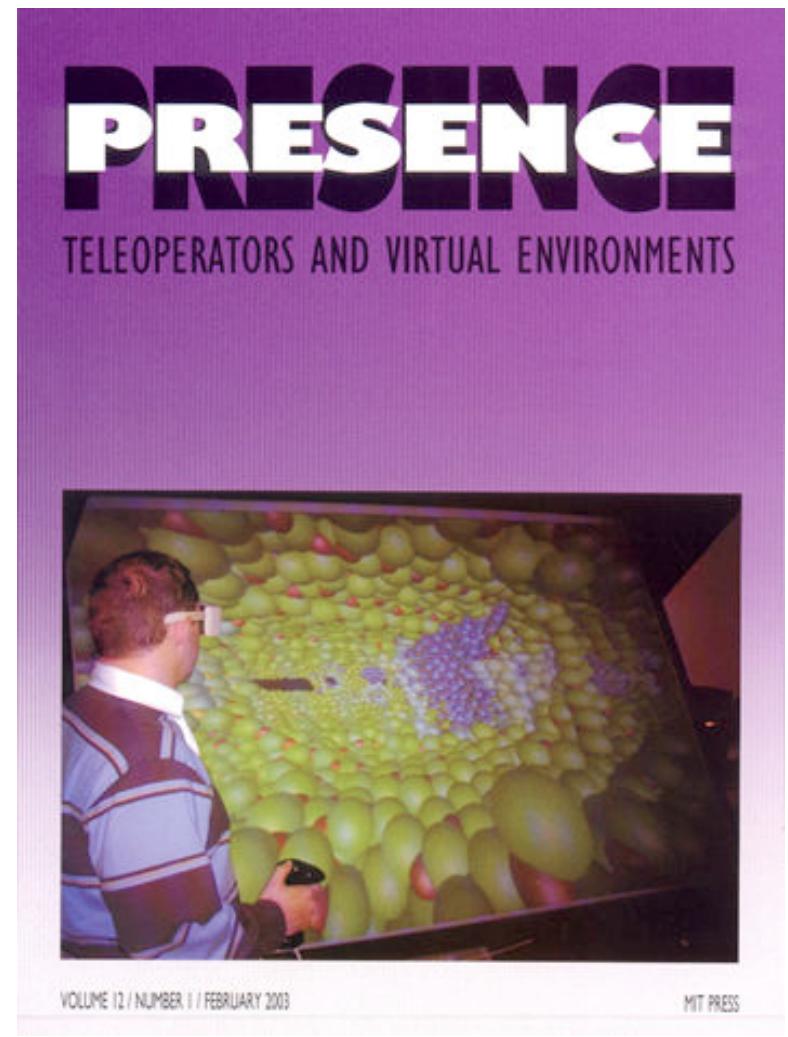

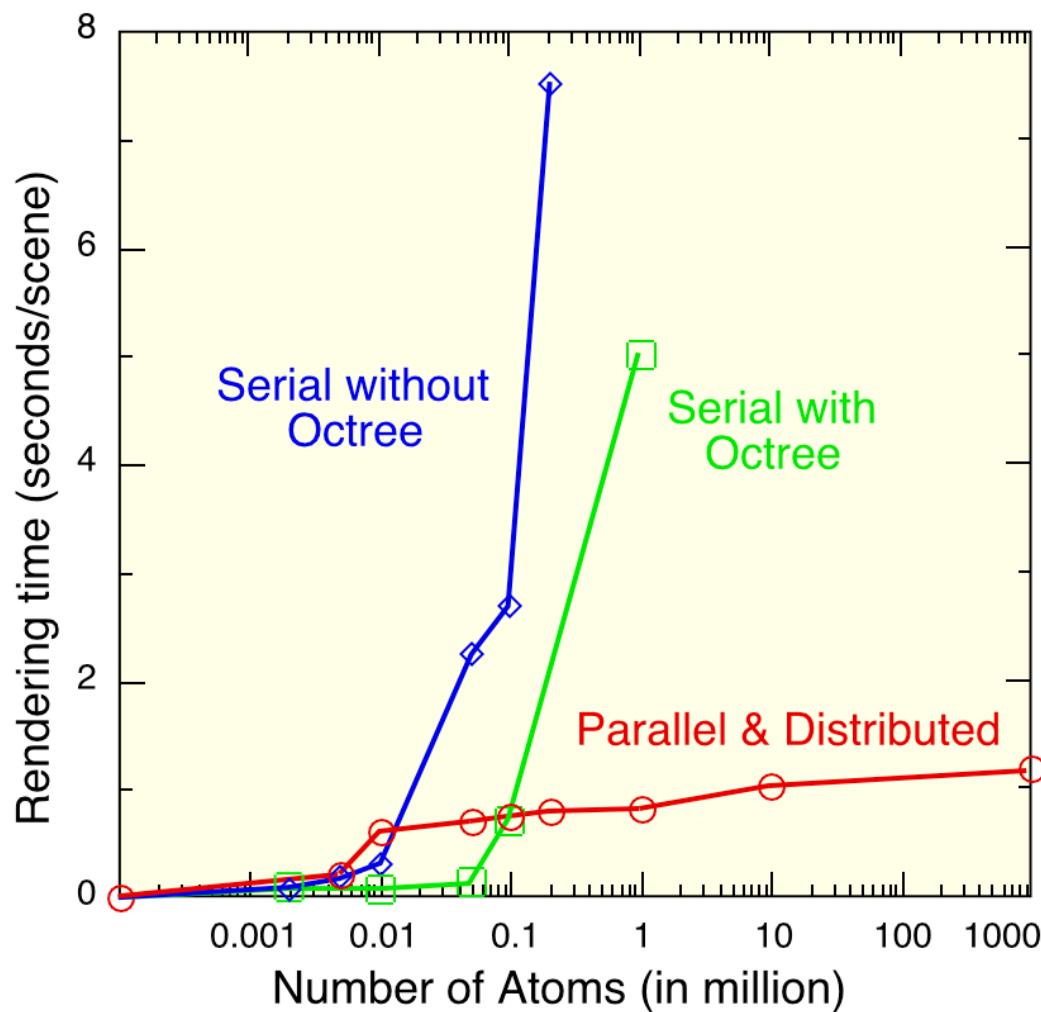

- Individual modules are multithreaded to reduce network or module latency
- Minimize latency due to inter-modular dependencies by overlapping the inter-module communication and module computation

- Instantaneously trained neural network (**CC4** [Tang & Kak, CSSP'98]) predicts the user's next position [Liu *et al.*, PDPTA'02]

Abstract

A scalable and portable code named Atomsviewer has been developed to interactively visualize a large atomistic dataset consisting of up to a billion atoms. The code uses a hierarchical view frustum-culling algorithm based on the octree data structure to efficiently remove atoms outside of the user's field-of-view. Probabilistic and depth-based occlusion-culling algorithms then select atoms, which have a high probability of being visible. Finally a multiresolution algorithm is used to render the selected subset of visible atoms at varying levels of detail. Atomsviewer is written in C++ and OpenGL, and it has been tested on a number of architectures including Windows, Macintosh, and SGI. Atomsviewer has been used to visualize tens of millions of atoms on a standard desktop computer and, in its parallel version, up to a billion atoms.

Program summary

Title of program: Atomsviewer

Catalogue identifier: ADUM

Program summary URL: <http://cpc.cs.qub.ac.uk/summaries/ADUM>

Program obtainable from: CPC Program Library, Queen's University of Belfast, N. Ireland

Computer for which the program is designed and others on which it has been tested: 2.4 GHz Pentium 4/Xeon processor, professional graphics card; Apple G4 (867 MHz)/G5, professional graphics card

Operating systems under which the program has been tested: Windows 2000/XP, Mac OS 10.2/10.3, SGI IRIX 6.5

Programming languages used: C++, C and OpenGL

Memory required to execute with typical data: 1 gigabyte of RAM

High speed storage required: 60 gigabytes

No. of lines in the distributed program including test data, etc.: 550 241

No. of bytes in the distributed program including test data, etc.: 6 258 245

Number of bits in a word: Arbitrary
